THE JOURNAL

OF THE

American Medical Association

A MEDICAL JOURNAL CONTAINING THE

OFFICIAL RECORD OF THE PROCEEDINGS OF THE ASSOCIATION, AND THE PAPERS READ AT THE ANNUAL
MEETING, IN THE SEVERAL SECTIONS, TOGETHER WITH THE

MEDICAL LITERATURE OF THE PERIOD

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES

GEORGE H. SIMMONS, M.D.

VOLUME XXXVII 37
JULY—DECEMBER
1901

CHICAGO
AMERICAN MEDICAL ASSOCIATION PRESS.
1901

GIFT OF
JOSEPH HENRY HEWITT.

"The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (and Sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except otherwise decided by special resolution."—TRANSACTIONS, 1851.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1901-1902

GENERAL OFFICERS

President—John A. Wyeth	New York
First Vice-President—Alonzo Garcelon	Maine
Second Vice-President—A. J. Stone	Minnesota
Third Vice-President—A. F. Jonas	Nebraska
Fourth Vice-President—James A. Dibrell	Arkansas
Secretary—George H. Simmons	61 Market St., Chicago, Illinois
Treasurer—Henry P. Newman	100 Washington St., Chicago, Illinois
Chairman Com. of Arrangements—G. F. Comstock	Saratoga Springs, N. Y.

BOARD OF TRUSTEES.

E. E. Montgomery, 1703 Walnut St., Philadelphia, 1902.
H. L. E. Johnson, 1821 Jefferson Place, Washington, D. C., 1902.
Joseph M. Mathews, Louisville, Ky., 1902
Miles F. Porter, Ft. Wayne, Ind., 1903.
E. Fletcher Ingals, 36 Washington St., Chicago, 1903.
W. L. Rodman, 1626 Spruce St., Philadelphia, 1903.
John F. Fulton, St. Paul, Minn., 1904.
T. J. Happel, Trenton, Tenn., 1904.
W. W. Grant, Denver, Colo., 1904.

JUDICIAL COUNCIL.

Term expires 1902: J. D. Griffith, Missouri; P. H. Bailhache, Marine-Hospital Service; J. E. Cook, Ohio; J. P. Lewis, Kansas; F. H. Wiggin (Secretary), New York; J. W. Irwin, Kentucky; Walter Wyman, District of Columbia. Term expires 1903: James R. Guthrie, Iowa; G. P. Gillespie, Tennessee; R. C. Moore, Nebraska; Ida J. Heiberger, District of Columbia; John B. Roberts, Pennsylvania; Charles S. Rodman (Chairman), Connecticut; S. L. Jepson, West Virginia. Term expires 1904: Geo. Cook, New Hampshire; H. H. Grant, Kentucky; John B. Murphy, Illinois; Philip Marvel, New Jersey; Louis H. Taylor, Pennsylvania; John L. Dawson, South Carolina; N. Fred Essig, Washington.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Frank A. Jones, Memphis, Tenn.; Secretary, Robert B. Preble, Chicago. Executive Committee—Frank Billings, Chicago; George Dock, Ann Arbor, Mich.; J. M. Anders, Philadelphia.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, J. H. Carstens, Detroit: Secretary, C. L. Bonifield, Cincinnati. Executive Committee—A. H. Cordier, Kansas City; W. E. B. Davis, Birmingham, Ala.; Henry P. Newman, Chicago.

SURGERY AND ANATOMY—Chairman, DeForest Willard, Philadelphia; Secretary, James B. Bullitt, Louisville. Executive Committee—W. J. Mayo, Rochester, Minn.; H. O. Walker, Detroit; A. J. Ochsner, Chicago.

HYGIENE AND SANITARY SCIENCE—Chairman, Arthur R. Reynolds, Chicago; Secretary, H. M. Bracken, Minneapolis, Minn. Executive Committee—W. C. Woodward, Washington, D. C.

OPHTHALMOLOGY—Chairman, Frank Allport, Chicago; Secretary, C. A. Veasey, Philadelphia. Executive Committee—Casey A. Wood, Chicago; H. V. Würdeman, Milwaukee; J. A. Lippincott, Pittsburg, Pa.

DISEASES OF CHILDREN—Chairman, H. M. McClanahan, Omaha, Neb.; Secretary, Frank X. Walls, Chicago. Executive Committee—H. E. Tuley, Louisville; Edwin Rosenthal, Philadelphia; Samuel W. Kelley, Cleveland, Ohio.

STOMATOLOGY—Chairman, A. H. Peck, Chicago; Secretary, Eugene S. Talbot, Chicago. Executive Committee—G. V. I. Brown, Milwaukee; M. H. Fletcher, Cincinnati; R. R. Andrews, Cambridge, Mass.

NERVOUS AND MENTAL DISEASES—Chairman, J. T. Eskridge, Denver; Secretary, F. Savary Pearce, Philadelphia. Executive Committee—Frederick Peterson, New York City; Hugh T. Patrick. Chicago; H. A. Tomlinson, St. Peter, Minn.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Henry W. Stelwagon, Philadelphia; Secretary, R. R. Campbell, Chicago. Executive Committee—W. T. Corlett, Cleveland: L. Duncan Bulkley, New York City; W. L. Baum, Chicago.

LARYNGOLOGY AND OTOLOGY—Chairman, G. Hudson Makuen, Philadelphia; Secretary, J. F. Barnhill, Indianapolis. Executive Committee—Emil Mayer, New York City; C. R. Holmes, Cincinnati; J. N. Mackenzie, Baltimore.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS—Chairman, George F. Butler, Alma, Mich.; Secretary, C. S. N. Hallberg, Chicago. Executive Committee—Thos. Hunt Stucky, Louisville; Leon L. Solomon, Louisville; N. S. Davis, Jr., Chicago.

PHYSIOLOGY AND PATHOLOGY—Chairman, Frank B. Wynn, Indianapolis: Secretary, Joseph McFarland, Philadelphia. Executive Committee—A. Stengel, Philadelphia; W. S. Hall, Chicago; L. Hektoen, Chicago.

GENERAL INDEX.

Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one head, etc., and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles, editorials, society reports, abstracts, and miscellaneous matter appearing in The Journal; the book notices, deaths, societies, marriages, authors, and titles of articles mentioned in the "Current Medical Literature" department are indexed and arranged under their separate headings instead of in the body of the "General Index."

  Medical Association, importance of, 856; see also ASSOCIATION.
  medical colleges, list of, with graduates, etc., 758
  medical literature, index of, 1722
  medical profession, reorganization of, 652
Amnesia, case of localized, 1601
Amphitheater clinic, teaching by, 771
Amputations, 1001
  intrauterine, 547
Amygdalitis, acute, 1064
Amyl nitrate, chloroform and, 605
  nitrite in spinal cocainization, 153
Anal pockets, 46
Anakhre, goundou or, 1354
Analgesia, anesthesia and, 1065
  combined, 1207
  spinal, 1144
  spinal, tropa-cocain in, 75
Anasarca, mechanical treatment of, 1713
Anastomosis, ureteroureteral, 254
Anatomy, relational, 836
  rational method of teaching, 731
Anders, J. M., Address on Practice of Medicine, 77
  J. M., respiratory conditions in gout, 997
Anderson, M., methods in preparation of teeth, 90
Andrews, R. R., address on stomatology, 3
Anemia, chronic, saline infusion in, 341
  intermittent pernicious, 1167
  of young children, 354
  pernicious, 410, 483, 577, 1144, 1414
  pernicious, enterogenic origin of, 228
  pernicious, in infants, 942
  splenic, 712, 1142, 1275, 1347
Anesthesia and analgesia, 1065
  aural, 474
Anesthesia, compress method of, by ethyl chlorid, 1497
  nausea, 411
  nitrous oxid and ether, 223
  nitrous oxid, asphyxial factor in, 1425
  Schleich's local, 948
  spinal, 220
  spinal, in obstetrics, 351
  teaching of, in medical schools, 778
Anesthetics for children, 1143
  notes on, 581
Anesthetization as a specialty, 348
  cardiac accidents after, 473
Aneurysm, aortic, 293, 866
  aortic, mechanical treatment of, 231
  cure of enormous dissecting, 462
  gelatin treatment of, 1623
  of mesenteric artery, diagnosis of, 1428
Aneurysms, gelatin treatment of, 459, 540
Angina, scarlatinal and diphtherial, defense against, 1499
  ulceromembranous, 1702
Angiomatosis, multiple cavernous, 1710
Angio sarcoma, cerebral, 66
Anilin in treatment of tuberculosis, 1282
Anilin oil, 1351
Animals, infection by, 599
Anisometropia, 1705
Ankylostomata duodenale, 451
Ankylostomiasis, 284, 1466, 1694
  case of, 1454
  mode of infection in, 117
Anopheles as hosts of trematode, 274
  influence of color on, 944

  H. G., syphilis and blastomycetic dermatitis, 104
Anthrax, danger of, from horsehair, 411
  in Ontario, 337
  treatment of, 1148
Anthropology, Congress of Criminal, 1199
Anthropometric data, evaluation of, 1645
Anti-bodies, microbian, practical diagnosis by, 666
Anti-diphtheria serum, tetanus from, 1255
Anti-malarial campaign, 923
Antimony, localization in organism, 1214
Antisepsis vs. asepsis, 1539
  surgical, 1208
Antitetanic serum, 339
Antitoxin, 537, 718
  care in manufacture of, 1323
  diphtheria, 283, 719
  expensive dosage of, 226
  use of large doses of, 124
Antituberculosis serum, 669
Antityphoid inoculation, results of, 1352
Antivenene, investigations upon, 1597
Antivivisection, misstatements of, 400
Antivivisectionists, method of, 702
Antrum abscess, 1144
  empyema of, in children, 532

Antrum, serous disease of, 474
Anuria and uterine carcinoma, 726
Anus, treatment of abnormal, 227
Aortic insufficiency, cured case of, 153
  insufficiency, valvular compensation in, 119
  lesions, 997
Aphasia, hysteric, 479
  treatment of motor, 608
Apomorphia, 1006
Apoplexy, 1419
  etiology of, 1419
Appendages, uterine, conservative treatment of, 489
Appendicectomy—surgical history, 1533, 1620
Appendicitis, 80, 471, 535, 1067, 1564, 1637, 1638, 1703
  and infectious disease, 1729
  avoidable causes of disaster in, 1480
  early operations in, 858
  ideals in, 66
  in female, 1729
  in life insurance, 1351
  intestinal parasites in, 477
  mortality of, 898
  rare complications in, 1056
  rarity of, in Mexico, 1357
  Tuffier's statistics on, 988
  unusual features of, 949
Appendix, auto-amputation of, 153
  extirpation of, 607
  function of, 852, 924

MEDICOLEGAL.

Agent's request, rendering services at, 280
Blood, by whom existence of, may be proved, 1060
  spitting or coughing of, 1344
Board of health can not be controlled by injunction, 716
Brain, condition of, may be shown by photograph, 529
Charitable hospital, risks taken by patient in, 936
Christian scientists, as to their reporting diseases, 404
City not liable for negligence of hospital surgeon, 60
Communications to volunteer physicians, privileged, 936
Compensation for pain and suffering, determining, 404
Compulsory vaccination, authority required for, 861
County board of health, power of secretary of, 795
Crimes against nature—evidence, 1557
Criminal abortion, its seriousness, proof, punishment, 61
Damages for loss of arm after amputation of fingers, 61
Deaths, expressions showing expectancy of, 1698
Discretion as to allowances for care of sick, 280
Dislocation, surgeon prevented from reducing, 1417
Dying declaration, what it is admissible to show, 344
Eddyites, mental soundness of, 1631
Employes, medical attendance for, 1698
Examination by expert oculist and aurist, requiring of, 794
Expert evidence, restriction of, in will cases urged, 597
Failure to make physician witness, 60
$15,000 for death of physician, 999
Flesh injury to foot, $2000 for, 1344
Free treatment, cannot bind state by promise of, 1072
Gestation, period of, 1060
Health officers, bases of recovery for services as, 657
Hip injury, $15,000 for, 1344
Imbecility, admissibility of non-expert opinion as to, 999
Improper treatment, aggravation of injury by, 1417
Injuries, $15,000 too much for, 597
  showing extent of, by movement of arm, 597
  to child, $20,000 for, 344
Injury case, admissible evidence of physician in, 1557
  permanent, physician's evidence of, 1557
  proof of, records, as to continuing, 530
  proof of, to "reasonable certainty," 936
Insanity as defense to crime, 1698
Kleptomania, opinions of experts, 1344
Knee, $300 for injury to, 1487
Leg, $8000 for loss of, below knee, 1344
Legs, $1500 for loss of, 529
  $1000 for breaking of, 716
Liability for neglect of patient during vacation, 405
  of married women for doctor's bills, 467
  of physician in local option territory, 1630
Libelous and not privileged communications, 344
License a "right," validity of act as to revoking, 657
Local option territory, liability of physician in, 1630
Malpractice case, requirements of, 530
  liability for negligence in amputation, 1487
  litigation, court terminates lengthy, 936
  sufficient evidence of, to go to jury, 61
Marriage to syphilitic, grounds for annulment of, 936
Medical book, reputation for skill as abortionist, 658
  examination, occurrences at, as evidence, 999
  examiner a general agent—fraud of, 1487
  examiner, and statements as to health, 1073
  examiner's knowledge—serious illness, 404
  preparations, right to make and use, 280
  services, data required to recover for, 716
  treatment, not required to refund cost of, 861
Mental injury from wilful wrong, 861
  suffering only, changes about allowing for, 468
[illegible] n procuring of, 139
[illegible] recovery for, 1072
Paid medical expert testimony of, 861
Passed suffering, statement of injured persons as to, 716
Personal injury case, particulars required in, 1204
Pesthouse, liability for injury of property by, 716
Physicians' claim, nature and limitations of, 1417
Poison case, attending physician as witness in, 794
Police power to regulate practice of medicine, 344
Postmort[illegible] fixing of [illegible] 1344
Powder [illegible] jurisprudence, 1000
Pregnant passenger, liability for injury to, 1487
Private examination by selected physician may be ordered, 467
Provision of law as to examination upheld, 1417
Quarantine power not authority to buy vaccine matter, 280
Rape case, no physician in attendance at trial of, 1204
Responsibility for crime, test of, 1698
Right to have hand examined by physician, 1487
Sanity, non-expert witness in inquiries as to, 860
School trustees must enforce board of health orders, 467
"Serious illness" in contract of life insurance, 999
Skill required; consultation; diagnosis; harshness, 1061
Skull and photograph admissible in evidence, 936
Smallpox suspects, city not liable for detention of, 1698
Specialist allowed his bill for "first" treatment, 1558
State board of health, disciplinary power of, 597
Summoning of surgeon by conductor of wrecking crew, 999
Survivorship, opinion evidence on, 1631
Temporary indigestion and informal consultation, 1204
Things patient may rely on—conflicting evidence, 1557
Twenty-five thousand dollars too large an award, 716
Unborn child, no damages recoverable for injuries to, 860
Validity of law requiring so much fat in cream sold, 139
Wife as witness to contract, physician calling, 1061
Woman's life, pecuniary value of, 597
X-ray photographs—notice of taking, 1631

THERAPEUTICS.

Abortion, 1557
Absorption of drugs by the bladder, 657
Acne in young, 794
  rosacea, 596
  vulgaris, 714
Agalactia, 1557
Albuminuria, acute, after scarlet fever, 1486
Alcohol and tobacco habits, prescriptions for, 1271
Alcoholism, 999
Alkaline douches, hot, in inflammatory diseases of uterus, 216
Alopecia areata, 1630
Amyl nitrite in seasickness, 140
Anemia, secondary, 793
Anesthesia, local, in the ear, 998
Angina pectoris, glonoin in, 59
Antipyrin in chorea, 1697
Antisepsis in gastro-intestinal disturbances, 215
Appendicitis, 528, 715, 1137
Asphyxia by drowning, 60
Aspirin as substitute for salicylates, 595
Breasts, diseased, proper method of bandaging, 935
  during pregnancy and lactation, 859.
Bronchitis, 1059, 1060
Bubo, 528
Burns, 215, 596, 793
Calcium chlorid for menorrhagia, 1137
Calomel as purgative, best way of prescribing, 529
Camphor in treatment of varicose ulcers, 715
  treatment of ulcers with, 1138
Cancer of larynx, palliative treatment of, 793
Carbolic acid in treatment of eczema, 596
Carcinoma of skin, 60
Catarrhal conditions of female genital tract, 1137
Chalazion, 793
Chancre, simple, 1630
Chilblains, 1697
Children, arthritic eczema in, 1698
Chloretone in pertussis, 595
  in surgery, 1416
Chordee, 528
Chorea, antipyrin in, 1697
  sodium cacodylate in, 999
Cocain in treatment of pain in gastric ulcer, 998
Colchicum, comparative value of the seed and root of, 793
Compresses, alcohol, in appendicitis, 715
Constipation, 279, 794
Cornea, dionin in diseases of, 59
Corns, salve to remove, 714
Coryza, acute, 715
Cough in tuberculosis, prescription for, 528
Cystitis, 715
Dandruff, 794
Dental caries, 1556
Dentifrice, astringent, 1344
Diarrhea in children, 140
  in typhoid, prescription to check, 1272
  obstinate, of tuberculosis, prescription for, 715
  of typhoid, 404
  summer, of children, 216
Diabetes, 1416
Dionin in diseases of cornea, 59
Diphtheria, convalescent stage of, 1557
Drowning, asphyxia by, 60
Dysentery, sulphur in, 794
Dysentery, 215, 1271
Ear, furuncle in, 998
  local anesthesia in, 998
Eczema, 215, 466, 715, 1486
  arthritic, in children, 1698
  carbolic acid in treatment of, 596
Empyema, 934
Epistaxis in old people, treatment of, 597
Ergot after labor, use of, 999
Erysipelas, 656
Female genital tract, catarrhal conditions of, 1137
Fissure of nipples, 794
Freckles, 60
Frost bite, 1697
Furuncle in Ear, 998
Galactorrhea, 860
Gastralgia, 1416
Gastric fermentation, 466, 998
Gastritis, acute, prescription for vomiting of, 794
Gastritis, menthol in, 998
Gastro-intestinal disturbances of infancy, 343
Glaucoma, 140, 1416
Glonoin in angina pectoris, 59
Goiter, 466, 1630
Gonorrhea, 1137
Gout, 59
Hair, prescription to prevent shedding of, 596
Hay fever, 278, 466
Hay fever, trichloracetic acid in, 596
Heart disease, 60
Hemorrhage, 1556
Hemorrhoids and ulcers of rectum, 794
Hemorrhoids, 279, 466, 1272
  treated by zinc chlorid, 1486
Hepatic disorders, functional, 1344
Hepatitis, malarial, 998
Hernia, umbilical, 657
Herpes zoster, 1272
Hot fomentations, method of applying, 1272
Hyperchlorhydria, 793
Hysteria, prescription for insomnia of, 794
Idiosyncrasies toward drugs, 1629
Inebriety, outside of hospitals, 528
Influenza, 1557
Insomnia of hysteria, 794
Iritis, specific, 1137
Jaundice, catarrhal, 1343
Labor, use of ergot after, 999
Lanugo and hairs, 656
Leg ulcers, 596
Lentigo, 60
Locomotor ataxia, 935
Mania, acute, 1343
Mastitis, 860
Medicines administered combined and individually, 1697
Meningitis, 716
  tubercular, sedative in, 656
Menorrhagia, calcium chlorid for, 1137
Menthol in gastritis, 998
Methylene blue in smallpox, 1416
Milk, deficiency of, 1557
Mosquito bites, 140
Mucous patches, specific, 279
Mustard in pneumonia, 794
Nephritis, scarlatinal, 715
Neuralgia, 1343
Neurasthenia, 529, 1137
Night sweats in tuberculosis, 1698
Odynophagia, orthoform to mitigate, 1630
Orthoform to mitigate odynophagia, 1630
Otitis media, suppurative, 140
Otorrhea, 1630
Paraldehyde and trional as hypnotic, 1138
Paralysis agitans, exercise in, 596
  agitans, 715
Paroxysms in pertussis, 596
Pelletierin tannate in tapeworm, 657
Peritonitis, tuberculous, 715
Pertussis, 595, 596, 656, 1272, 1697
Petroleum, acute articular rheumatism treated by massage with, 1487
Pharynx, specific ulceration of, 528
Pityriasis of face and eyebrows, 935
Pleurisy, purulent, 934
Pneumonia, croupous, 998
  mustard in, 794, 935, 1203
Pregnancy, hyperemesis of, 59
Prescription writing, 1343, 1415, 1485, 1556, 1620
Prickly heat, 279
Prostatitis, chronic, local treatment of, 998
Pruritus ani, 596
Pruritus, 935, 998
  pudendi, diabetic, 1137
  vulvæ, 935
Psoriasis, 999
Puerperal eclampsia, 59
Rectum, hemorrhoids and ulcers of, 794
Rheumatism, 595, 999, 1487
Rhinitis, acute, 1486
Rhus toxicodendron poison, 596
Salivation following ether narcosis, 657
Salol in smallpox, 1416
Santonin in tabetic pains, 140
Scarlatina, graver forms of, 1556
Scarlet fever, throat in, 1272
Sciatica, 60
Seasickness, amyl nitrite in, 140
Smallpox, 1416
Sodium bicarbonate in vomiting of pregnancy, 140
  cacodylate in chorea, 998
  formate in pneumonia, 935
Sore throat, 1272
Sparteln, proper method of using, 998
Stomach, ulcer of, 466
Stricture, 1630
Sulphur in dysentery, 794
Synovitis, rheumatic, 935
Tabes dorsalis, 657
Tabetic pains, santonin in, 140
Tannin and bromin in pruritus, 998
Tapeworm, 139, 529
Tenia solium, 139
Tetanus, carbolic acid in, 1343
Throat, in scarlet fever, 1272
Thrush complicating dentition, 467
Tic douloureux, 1343
Tinea tonsurans, 596
Tobacco and alcohol habits, 1271
Tonic and eliminant in infectious diseases of children, 59
Tonsillitis, 1630
Toothache, 467
Toxemia of pregnancy, 999
Tracheo-bronchitis in children, 1486
Trichloracetic acid in hay fever, 596
Trional and paraldehyde as hypnotic, 1138
Tuberculosis, intestinal, in infants, 657
  cough and pain in, 1137
  night sweats in, 1698
Typhoid in children, treatment of, 466
Typhoid, 403, 1272
Ulcer, gastric, cocain in, 998
  gastric, 216, 466
  varicose, 596, 935
Ulceration, specific, of pharynx, 528
Ulcers treated with camphor, 715, 1138
Umbilical cord, 140
Uterus, inflammatory diseases of, hot alkaline douches in, 216
Vaginal diseases, 1344
Vomiting of pregnancy, sodium bicarbonate in, 140
Warts, 60, 1416
Whitlows, 934
Zinc chlorid, in hemorrhoids, 1486
Zona, 1272

AMERICAN MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index covers titles and subjects of original articles published in the medical journals of the United States and Canada during the past six months. The titles, and the journals in which they appeared, were published weekly in the Current Medical Literature department, to which references are made. The figures in ( ) refer to the paragraph; the number following, to the page in The Journal. For instance, "Abdomen, gunshot wounds of, (119) 1274" refers to page 1274 of The Journal, on which is found opposite paragraph 119, the title of paper and name of author, viz., "Gunshot Wounds of the Abdomen. E. F. Robinson." This title is listed under the journal in which the article appeared: "Kansas City Medical Record, October." Titles of articles which appeared in The Journal are indicated by an asterisk (*) before the page number.

Abdomen, contusions of, (87) 1419
  gunshot wounds of, (119) 1274
  pendulous, operation for relief of, (126) 1206
Abdominal and pelvic pathology, nerve reflexes due to, (145) 1063
  cases, report of, (128) 142
  cavity, bile in, (9) 598
  cavity, foreign bodies accidently left in, (130) 1206, (55) 1488
  disease, right-side, cases of, (21) 141
  incisions, on making and closing, (162) 1206
  operations, drainage after, *20
  operations, pus in, (38) 598
  operations, technic of aseptic, (67) 937
  section, hernia ten years after, (129) 1062
  sections in general practice, (47) 62
  sections, urinary analysis in, (138) 1206
  surgery, some thoughts on, (109) 1206
  viscera, demonstration of model of, (58) 406
Abortion as a disease and a crime, (117) 1419
  criminal, (121) 1001
  infection as etiologic factor in, (80) 1062
  management of, (94) 1632
  resulting in acute septicemia, (129) 1001
  streptococci infection complicating, (127) 599
  treatment of, (45) 598, (60) 1139
  tubal, (76) 141
  uterine hemorrhage following, (131) 1001
Abscess, appendicular, (22) 217
  brain, cases of, (70) 1345
  cerebellar, (61) 469
  cerebral, (8) 468
  congenital, of internal genitals, (29) 937
  dissecting, of abdominal wall, producing deformity, *1458
  epityphlitic, observations in, (99) 406
  in posterior mediastinum in connection with Pott's disease, (15) 1631
  intra-peritoneal, of abdomen, (179) 863, (161) 1140
  of ethmoid and antrum of Highmore, (63) 62
  of kidney, case of, (89) 1062
  of larynx, (173) 1275
  of liver, (129) 1206
  of lung, pneumotomy for, (27) 345
  pelvic, (153) 63
  pulmonary, surgery of, (25) 1418, (6, 72) 1488, (26) 1558
  retro-peritoneal, operative management of, (98) 406
  subphrenic, (86) 599
  tubo-ovarian, (51) 468, (82) 717
Abscesses, pelvic, appendiceal, infrapubic opening of, (86) 1139
Abscesses, purulent and fecal, (37) 1205
  retropharyngeal, after otitis media purulenta, (66) 1345
Abstinence, total, medical profession and, (92) 862
Accidents, scientific study of, (52) 1699
A. C. E. mixture and ethyl bromid in operations for adenoid vegetations, (2) 1345
Acetanilid, considerations concerning toxicity of, (124) 142
Acetone, bearing of alimentation on excretion of, ([illegible]) 346
Acid, carbolic, (59) 1727
  carbolic, poisoning, (117) 1062
  intoxication, (66) 1559
  intoxication of diabetes, (99) 1274
Acne vulgaris, (153) 346
Acromegalia, (32) 141, (156) 470, (142) 938
Acromegaly, unusual features in, *887
Actinomycosis in man, (137) 142, *(13) 658, (38) 1558*
Actinotherapy in cutaneous medicine, *21, (15) 217
Acute diseases, nervous complications in, (161) 938
Addison's disease, (92) 1001
  disease treated with suprarenal extract, (37) 141
  disease, tuberculosis and, (14) 1345
Address, Albany College of Pharmacy, (78) 1632
  Albany Hospital Training School for Nurses, (53) 1000
  Albany Medical College, (37) 1345
  American Dermatological Association, (122) 406
  American Medical Association, (135) 599, *1431
  American Medico-Psychological Association, (97) 718

Filaria medinesis, case of, (3) 1273
Filtration or gland process, the, (92) 282
Fishes, cutaneous sense organs of, (141) 1206
Fissure of brain, trap-door operations in, (154) 470
  the summit, (12) 598
Fistula, appendiceal, (25) 1345, (65) 1488
  fecal, treatment of, (60) 1700
  in ano, (84) 281, (152) 863
  rectal, (125) 282, (64) 1139
  vaginal, (112) 1700
  vesico-vaginal, (136) 1419
Fistulæ, rectal and anal, (44) 1488
  pleural, following operations for empyema, (150) 1419
  vesico-vaginal, remarks on, (135) 1560
Flagella staining with night blue, (68) 1559
Flexion and adduction, forced, in sensitiveness of hip-joint, (33) 217
Flint murmur in aortic insufficiency, (73) 1418
Fluorin poisoning, chronic, (20) 217
Follicles, rebellious form of diseases of, treatment of, (100) 1139
Food as etiologic factor in disease, (14) 1488
  laws, unjust, (115) 1489
  products from diseased animals, *1715
  study of, consumed, by four members of Harvard boat crew, (28) 62, (25) 141
Foods, artificially prepared, their nutritive value and dietetic application, *1094
  dietetic and gluten, of commerce, (32) 1138
  food economics and food adulteration, (49) 406
Foot, abnormal condition, as cause of knee symptoms, (92) 346
Forceps, axis-traction, (143) 469
  cutting, for operating in postnasal space, (122) 469
  obstetrical, use of, (181) 142
Forearm, congenital defect of, (8) 1699
  treatment of fracture of, (73) 1727
Foreign bodies accidentally left in abdominal cavity, (130) 1206, (55) 1488
  bodies in ear, (76) 1727
  bodies in esophagus and trachea, (151) 1701
  bodies of nose and ear, (10) 937
  bodies passed from rectum, (45) 1139
  bodies, removal of, from air-passages, *1077
  bodies wounding the eye, (43) 1488
  body in eye, location of, by *x*-rays, (148) 63
  body in eyeball for eighteen years, (141) 1275
Formic aldehyde in tuberculosis, (22) 717
Fracture, compound comminuted, of humerus, (165) 1206
  compound, of lower jaw, (145) 938
  of carpal end of radius, (42) 659
  of forearm, treatment of, (73) 1727
  of jaw, intradental splint for, (79) 938
  of neck of femur, treatment of, (56) 218
  of skull, (61) 862
  of skull, compound comminuted depressed, (5) 1699
  simple, of vault, with meningitis, 834

Fractures, ambulatory treatment of, (61) 281, (51) 659
  ambulatory treatment of, involving hip-joint, (151) 142
  compound, of extremities, suggestions for treatment of, (54) 345
  general considerations of, (58) 281
  femur and humerus, (104) 718
  of femur, treatment of, with ambulatory pneumatic splint, *1605
  of humerus, suggestions bearing on, (57) 1062
  of neck, anatomical treatment of, *1661
  of nose, (140) 63
  of shaft of femur, treatment of, (166) 1275
  of skull, observations on, (133) 1206
  ununited, (101) 1062
French Congress of Surgery and Urinology, (37) 1727
Frenum, intermaxillary, means of reducing overgrowth of, (59) 1000, (35) 1061
Frost-bite of cornea, (31) 1632
Fuller, Samuel, pilgrim, doctor and deacon, *1298
Funeral delayed in Philippines, (96) 346
Fusel-oil poisoning with reference to copper-reducing substances in urine, (19) 530

Gall bladder, architecture of, (121) 63
  bladder, surgical malposition of, (60) 1488
  duct, hydraulic pressure to open common, (125) 1062
Gallstone, a large, *265
  in common duct, (107) 1559
  unusual case of, (190) 142
Gallstones, (49, 50) 62, (94) 346
  cholecystectomy for, (32) 1632
  cholecystitis and cholangitis as complication of, *1453
  clinical history and diagnosis of, (164) 863
  diagnosis of, (146) 1001, (1) 1631
  duodenal stenosis due to, (144) 863
  etiology of, (163) 863
  fat necrosis in connection with, *1176
  when to operate upon, (8) 795
Galvanism for uterine hemorrhage, (121) 1559
Ganglion cells, studies in morphology of, in rabbit, (98) 1274
  resection of superior sympathetic cervical, (16) 62, (59) 345
  superior cervical sympathetic, in glaucoma, *1588
Gangrene, carbolic acid, (119) 218, (33) 1488
  case of multiple, *445
  emphysematous, caused by aerogenes capsulatus, (7) 405
  in newborn, (45) 1727
  of bowel wall, (37) 1205
  senile, case of, *1319
  symmetrical, (145) 142
Gas and gas cysts of central nervous system, origin of, (104) 862
Gasserian ganglion, examination of, by Nissl's method, (98) 862
  ganglion in cadaver, removal of, (28) 217
Gastrectomy, partial, for hemorrhagic ulcer, (22) 1138
Gastric *secretions* in chronic rheumatism and rheumatoid arthritis, (33) 468
  surgery, (73) 1488
  ulcer, indications for operation in, (15) 717
  ulcer, surgical aspect of, (76) 659
Gastritis, chronic, (138) 599
  complicated with myasthenia gastrica, (22) 598
  menthol in treatment of, (129) 863
Gastro-enteric infection in infants, treatment of, (38) 468
Gastroenterostomy, (153) 938
  and intestinal resection, (83) 1489
  death after, (39) 141
  indications for, (94) 1419
  vicious circle after, (18) 468, (21) 530
Gastro-intestinal tract, experimental surgery of, (46) 1699
Gastro-jejunostomy in gastrectasis, (31) 717
Gastrostomy, (71) 62
  operation, modified, (134) 1139
Gelatin in hemorrhage, (47) 717
Genital organs, tuberculosis of female, (78) 1205
Genito-urinary diseases, symposium on, (165) 863
  organs, briefs on surgery of, (155) 63, (125) 938
  surgery, anesthesia in, (62) 281
Genuvalgum, (100) 531
German measles, lamellar desquamation in epidemic of, (96) 938
  surgical clinics, impressions of, (128) 1274
Germany, no thieves in, (62) 659
Gestation, ectopic, (87) 346, (74) 531, (64) 1205, (39) 1757
  triple ectopic, (105) 1700
  ruptured ectopic, successfully operated on, (53) 1345, (137) 1633
Giacomini, Carlo, central fissure of, (31) 658
Gingivitis, simple, etiology and treatment of, *161
Girl, American, health of, (139) 1489
Girlhood, gynecological and obstetrical significance of, *174
Girls, measurements of, in private schools, (5) 468
Glanders, diagnosis of, by Strauss method, (67) 1559
Glandular fever, (138) 1346
Glaucoma, removal of superior cervical sympathetic ganglion for, (59) 345
  subacute, resection of ganglia for, (144) 1275
  superior cervical sympathetic ganglion in, *1588
Glioma of the brain, (61) 1139
  of retina, (65) 281, (84) 938, (74) 1700
Gluten and diabetic foods of commerce, (32) 1138
Glycerinated lymph; experiences with, (19) 1558
Glycosuria, transient or simple, (69) 218
Goiter, complicated by stenosis of trachea, (70) 62
  pathology of, (79) 1700
Gonococcus and its toxin, (17) 1000
Gonorrhea, (76) 598, (37) 1488, (50) 1699
  acute, (11) 1488
  acute, modern treatment of, (75) 218
  acute, protargol in, (46) 1727
  acute, report of special committee on, (113) 938
  as social problem, (139) 346
  chronic, (76) 218
  chronic, and post-gonorrheal urethritis, (23) 141
  chronic, dilating irrigations in treatment of, (62) 1139
  comparative treatment of, (61) 659
  etiologic factors in, (165) 863
  in boys, *827
  in women, (166) 863
  is it local or constitutional affection? (82) 599
  local treatment of, (31) 937
  sequelæ of, (169) 863
  special committee of American Medical Association regarding, (137) 1206
  therapeutics, capital sin of modern, (39) 717
  treatment of, (25) 345, (136) 407
  urethritis or, (122) 1139
  what are the consequences of, (103) 406
Gonorrheics, plea for, (126) 163
Good of the order, for the, (90) 1062
Gout and obesity, respiratory conditions dependent upon, (32) 1273
  and rheumatism, (96) 1559
  irregular, and hepatic inadequacy, (142) 469
  prevalence and treatment of, (176) 1275
Government duty, a (149) 1701
Granular lids, (24) 1488
Graves' disease, consideration of, ([illegible]) 863

prostatic, prostatectomy in, *1151
prostatic, to urination, (63) 1488
of bowel by enterolith, (56) 1274
Obstructive diseases of lower bowel, (74) 1062
Occipito-posterior positions, (1) 795, (34) 1061, (78) 1488
Occlusion, congenital, of duodenum, (59) 62
Occupation as affecting death-rate, (102) 406
Octogenarian, paraphimosis in an, (33) 1727
Ocular affections and systemic diseases, relationship between, (51) 937
affections in xeroderma pigmentosum, (49) 1062
affections of childhood, (16) 1205, *(72)* 1700
muscles, nasal condition affecting, (16) 405
Oculist, *when should he be consulted,* (26) 1488
Oil of cedar, poisoning with, (12) 1631
Oils, lupus treated with, (138) 1001
Old age, disease and, (89) 531
Onychia, syphilitic, (167) 863
Operate, who shall, (149) 938
Operating case, compact, for railway surgeons, (150) 142
outfit, portable, (55) 406
Operative surgery, modification of, (2) 1558
work, limitations of, (17) 598
Ophthalmia neonatorum, (105) 469, (68) 659, (104) 1274, (61) 1700
Ophthalmic science and art, present position of, (29) 1488
Ophthalmology, general practitioner and, (136) 863
new findings in, (102) 141, (42) 345
report of proceedings of section on, A. M. A., (111) 346
section of, *977
Ophthalmoplegia, hereditary binocular, (91) 599
Ophthalmoplegia, remarks on diagnosis of, (82) 1418
Ophthalmoscope, fiftieth anniversary of invention of, (159) 863
in medicine, (2) 61
new electric, (93) 1700
Ophthalmoscopic diagnosis of Bright's disease, (97) 1062
Opium and its alkaloid morphin, (126) 142, (91) 406
poisoning, case of, (95) 1274
some adjuvants and corrigents of, (140) 1001
Oral indications of physical conditions, (94) 469
Orbit, implanting of glass ball in, *978
Organic evolution, physiologic theory of, (142) 1206
Organotherapy, ovarian, (57) *406*
Orthodoxy, therapeutic, (93) 406
Orthopedic surgery, notes in, (122) 1206
surgery, teaching of, in U. S., (106) 406
Osmotic pressure and relation to uremic manifestations, *256
Osseous *malformations, modern aspects of congenital,* *966
Osteitis deformans, (125) 346, (74) 1418
Osteo-arthritis of spine, cast of, (44) 717
Osteoclasis for correction of deformities of legs, (67) 62
of elbow, (137) 1489
Osteoma, multiple, (130) 1419
of orbital plate of frontal bone, (58) 1700
Osteomyelitis, (39) 1274, (138) 1633
involving superior maxilla, (51) 218
of femur, (68) 1418
Osteotomy, subtrochanteric, for deformity following hip disease, (17) 140
Otitis, (70) 1418
media, acute, treatment of, (15) 1061
media, bacteriology of, (20) 1418, (22) 1488
media, bilateral, pyemia caused by, (69) 1345
media, chronic, complicated with mastoid cholesteatoma and cranial abscess, (104) 599
media following influenza, (29) 1418, (89) 1419
media mucosa, (30) 937
media purulenta, retropharyngeal abscesses after, (66) 1345
media, tuberculous, (13) 1138
Otology, address in, (64) 1700
Otomycosis, (113) 141
Otorrhea, (136) 142, (143) 938
Ounce of prevention, the, (43) 531
Ova, progressive change in, in mammillian ovaries, (97) 862
Ovarian plexus and its controlling influences, (43) 1727
surgery, results of, *357
symptoms and their value, (43) 598
Ovaries and tubes, conservative surgery of, (52) 1345
conservation *of, (62) 1062,* (115) 1274
salpingostomy, resection and ignipuncture of, (103) 1559
Ovary, anatomy and function of, and some of its diseases, (36) 937
prolapsed, simulating direct inguinal hernia, (46) 1274
studies of structures of, (53) 937, (120) 1206
Ovariectomy *complicated by aneurysm of aorta,* (46) 218
Oxalic acid, origin of, (8) 598
Oxygen gas in diseases of chest, (55) 1345
Oxphenylethylimin in pancreatic digestion, on, (65) 1559
Ozone, inhalations of compound, in tuberculosis, (159) 1140, (130) 1633

Pain, diagnostic value of, in intra-abdominal and pelvic diseases, (74) 598
relief of, (112) 63
Palsy, complete unilateral oculomotor, (69) 141
Pampiniform plexus, fatal hemorrhage from varix of, *199

Pancreas, annular, (16) 1558
  cystadenoma of, (8) 405
  in diabetes mellitus, histopathology of, (73) 1700
Pancreatitis, acute, and fat necrosis, (104) 1559
  hemorrhagic, (134) 63, (126) 1700
Panhysterokolpectomy, (16) 1138
Panophthalmitis, double, of septic origin, (5) 1000
  is it justifiable to enucleate during acute stage of, (117) 938
Pantherapist and aestherapeutics, (57) 141, (27) 937, (154) 1701
Papilloma of larynx, thuja occidentalis in removal of, *326
Papillomatous growths of soft palate, (138) 938
Paraffin, subcutaneous injection of, (41) 937
Paraffins, use of solid and liquid, on culture media to insure anaerobic conditions, (119) 863
Parakeratosis variegata, case of, (63) 717
Paralyses, laryngeal, (15) 1726
  ocular extrinsic, *1374
Paralysis, abductor, with returning singing voice, (82) 1346
  and dystrophy of muscles, (76) 62
  facial, (145) 346
  facial, supraorbital reflex in, (24) 1558
  infantile and spastic, results of tendon grafting in, (40) 1205, (41) 1418
  multiple unilateral cranial nerve, (39) 1558
  ocular extrinsic, table of, *1366
  oculomotor and trifacial, (18) 281
  of bladder and rectum from injury, (128) 863
  progressive unilateral ascending, (92) 1206
  recurrent, with complete aphonia, (82) 1346
  rules for detection of paretic muscle in, (143) 1275
Paranephritis, chronic indurative, after chronic suppurative pyelitis, (99) 1346
Paraphasia, case of anomia and, (9) 1345
Paraphimosis in an octogenarian, (33) 1727
Paraplegia, ataxic, (83) 1062
Parasite, flagellated malarial, (28) 468
  tertian malarial, conjugation in a sexual cycle of, (18) 405
Parasites in blood, (116) 142
  malarial, structure of, (52) 717
Parasitic diseases of nails, (56) 1418
Paré, Ambrose, life and work of, (33) 1138, (35) 1205, (10) 1275
Paresis, modern views on, (180) 1275
Paretic dementia, etiology of, *832
Paris, visit to hospitals of, (59) 1274
Paroccipital, fissural integrality of, (108) 218
Parotid gland, suppuration of, with pus in external auditory canal, *450
Parotitis, double, (124) 1419
Parturient canal, can injuries to, be avoided during normal labor, (137) 1063
Pasteur, Louis, life and work of, (73) 659
Pathogenic microbe and destruction of rats, (102) 938
Pathologic work at city hospital, (116) 938
Pathology and bacteriology, address before Section on, *1431
Pectoralis major muscle in man, observations on, (130) 63
Pediatrics, surgical, advancement of, *155
Peking clinic, morning in, (148) 1140
Peliosis rheumatica, (30) 658. (29) 1138
Pelvic and abdominal surgery, odd cases in, (115) 1559
  and hepatic diseases in women, (119) 142, (124) 346
  floor, lacerations of, and their repair, (121) 863
  inflammation in female, (5) 1558
Pelvic injuries, (86) 1062, (66) 1418
  surgery, accidents and complications of, *25
  surgery, simple methods in, (135) 407
Pelvimetry, (138) 1063
Pelvis, female, inflammatory exudates in, (118) 531
  generally contracted, symphysiotomy on, (81) 1062
  vaginal section for pus in, (34) 1699
Pemphigus and erysipelas in infants, (37) 717
Penis, double, combined with exstrophy of bladder, (28) 937
  statistical digest of epithelioma of, (76) 406
Pennsylvania Brigade Hospital tent, (91) 1274
Pepper, William, memoir of, (73) 406, (65) 659
Peptomangan, Gude's, clinical report on, (130) 1489
  therapeutics of, (140) 1489
Perforation, pistol-shot, of intestines, (173) 863
Pericarditis, clinical observations in, *1503
  etiology of, *1510
  pathology and pathogenesis of, *1507
  role of myocardium in, *1577
  suppurative, diagnosis of, (38) 1418
  suppurative, following appendicitis, (134) 1206
  suppurative, observations on, (39) 1418
  treatment of, *1583
  tubercular, *1580
Pericardium, adherent, *1578
Periendothelioma of dura mater, involving cranial nerves, (91, 141
Perineorrhaphy, intrapelvic intravaginal, without loss of tissue, (43) 217
Perineum, chronic laceration of, (51) 1559
Periosteal elevator, a, (85) 141
Periosteum, growth of new bone from, (30) 1138
Periscopic lenses, (55) 1062
Peritoneal infections, elimination of, and prevention of surgical peritonitis, *360
  section, prevention of complications after, (147) 1001
Peritoneum, gelatinous disease of, (73) 345
  tuberculosis of, (91) 1559
Peritonitis, acute, (16) 598
  acute, diagnosis and treatment of, (44) 406, (79) 599
  acute, etiology of, (72) 218
  acute tubercular, with strangulation of appendix, (46) 141
  general, (37) 1205
  general septic, (129) 346
  pelvic, (128) 1001, (154) 1206
  pelvic, and exudates, (38) 405
  pseudomyxomatous, (73) 345
  surgical, prevention of, and elimination of peritoneal infection, *360
  tubercular, (52) 469, (46) 862, (33) 1205, (11) 1273, (59) 1700
  tubercular, congenital malformation leading to error in diagnosis of, (64) 1062
Perkins, Maurice, sketch of late, (69) 531
Pest, biology of the bacillus of, (99) 862
Petroleum compounds given medically, inertness of, (22) 658
Phalanges of hands and feet, rare variation in, (68) 717
Pharmacist, ideals of, (144) 1419
  tribulations of, (107) 141
  to physicians, relations of, (30) 345
Pharmacologic action of drugs, (120) 1139
Pharyngitis, follicular, so-called, (108) 1633
  membranous, types of, *186
Pharyngomycosis, (67) 1001
Pharynx, unusual foreign body in, (86) 1346
Phenalgin in neuralgia, (51) 1000
Phenomena which would prompt us to look for disease of kidney, (96) 1489
Philippine Islands from health standpoint, (125) 1346
Philippines, dysentery in, (4) 598
  sanitary work in, (3) 1205, (12) 1418
Phlebitis following abdominal operations, (27) 281
Phlegmon of pharynx and larynx, (100) 1559
Phospho-therapy and nerve-exhaustion, (159) 938
Photography in medicine, (163) 1701
Photo-mechanical reproduction, (19) 281, (22) 345
Phthisis, alcohol in, (60) 1345
  home treatment of, (52) 345
  secondary infection in, (28) 1345
  silver nitrate injections in, (29) 658
Physical culture in children, (72) 1139
  life and perversion of physical acts in relation to the same, (138) 1140
  development, unbalanced, relation of, to pubertal morbidity, *691
Physician and his status, (140) 142
  and pharmacist, (106) 599
  and the public, (141) 938
  as sanitarian, (180) 142
  as sociologic factor, (15) 1345
  in public affairs, influence of, (93) 346
  in relation to dispensing of medicine, (69) 1001, (17) 1273
  little things that should be observed by, (111) 938
Physicians and municipal affairs, (94) 1206
  and surgeons, legal duties of, (99) 346
  duties of, to each other, (112) 1346
  early, of Los Angeles, (137) 1700
  leading, (109) 1489
  successful, types of, (27) 1000
  to community, ethical and sociologic relations of, (96) 1206
Physiology and pathology, problems of, (8) 1000
  what constitutes good text-book in physiology, (51) 1274
Phytolacca decandra, therapy of, (121) 1346
Pig's intestine, development of, (115) 63
Piles, carbolic acid in treatment of, (36) 1699
Pilocarpin hydrochlorate in croup, (7) 217
  in inflammation of interior of eye, (48) 717
Pineal region, morphology of, (135) 1700
Pistol-shot wounds, (10) 1061
  shot wound in pregnant woman, (9) 1631
Placenta, adherent, (80) 1001
  previa, (34) 141, (134) 938, (92) 1062, (97) 1419, (85) 1489, (65) 1727
  previa, Cesarean section for, *495, (54) 1345
  previa, management of, (98) 282, (122) 346
  previa marginalis with infection of placenta before delivery, (37) 405
  retained, in primaparæ, (146) 1700
  retained, unusual case of, (83) 1727
Plague, bubonic, pathology and bacteriology of, (41) 717, (67, 68) 1139
  bubonic, was epidemic in Athens, B. C. 430, (20) 1061
  in Manila, (81) 599
  in New South Wales, synopsis of report of, (117) 346
  on clinical aspects of, (66) 1139
  reports, (86) 1205
Plagues of the world, historical sketch of, (81) 406, (148) 1701
Plaster-of-Paris jacket, (55) 62
Pleura, lungs and, diseases of, (44) 62
Pleural effusion, (98) 938
Pleurisy in children, (105) 599
  infantile, with effusion, (9) 1488
  tubercular, (see pneumonia)
Pneumatic splint, ambulatory, for fractures of femur, *1605
Pneumectomy, some experiments in, (72) 659
Pneumonia, (135) 469, (135) 1633
  abortive treatment of, *1240
Pneumonia, acute lobar, (165) 63, (28) 530, (26) 1418, (145) 1419
  apex, significance of, (105) 1062
  atypical, and tuberculosis, (18) 62
  carbonate of creosote in, (1) 1345
  creosote in, (71) 1727
  croupous, observations in treatment of, (24) 1345, (123) 1419
  croupous, typhoid complicated by, (79) 469
  hydriatic management of, (152) 1419
  in children, treatment of, (107) 1274
  lobar, insolation complicated by, (98) 1001
  lobar, with hyperpyrexia, (19) 217
  lobular, bacteriology of, (70) 531
  microscopic aids in diagnosis of, (58) 62
  observations on treatment of, (63) 1559
  pericarditis, and tubercular pleurisy, practical ideas on treatment of, (146) 1063
  potassium bicarbonate, (139) 1560
  protracted influenzal, in infancy, 560
  surgery of pulmonary abscess, gangrene and bronchiectases following, (26) 1558
  treated by antipneumococcus serum, (10) 1726
  treatment of, (53) 62, (168) 142, *1237, (77) 1727
  unusual sequela of, (127) 1700
  value of venesection followed by saline injection in, (96) 1001
  veratrum viride in, (84) 1559
  with effusion, (74) 281
Pneumothorax, (124) 1633
Pneumotomy for abscess of lung, (27) 345
Poisoning, chronic arsenical, in infant, (97) 938
Poliomyelitis, acute anterior, in adult, (56) 937
Polyneuritis, malarial, (120) 599
Polypi, aural, (72) 1345
  rectal, in children, (95) 938
Population, congestion of, as affecting death rate, (96) 218
Porro-Cesarean section, (108) 1001
  section for placenta previa centralis, (32) 217
Porto Rico, climate and diseases of, (24) 217
Position of woman during delivery, *613
Post-graduate instruction in sanitary science, need of, (55) 717
  study in London, (82) 62
Postmortem recollection, a, (108) 1062
Post-nasal discharge, chronic, (109) 346
Post-operative sequelæ and conservative gynecology, (37) 598

  - facts learned in management of, (34) 1558
  - in country practice, (135) 1001
  - in infancy and childhood, symptoms of, *440
  - in North Carolina, (111) 531
  - infantile, (9) 658, (47) 862
  - infection without lesion of intestine, (53) 406
  - in rural districts of North Carolina, (189) 142
  - in syphilitic, (65) 1139
  - in tuberculous patient, (16) 468
  - intestinal obstruction from, (85) 1205
  - intrarectal injections of normal salt solution in, (79) 218
  - late epidemic of, (114) 346
  - management and treatment of, (48) 1488
  - management of, in country practice, (113) 1346
  - modern methods in management of, (26) 795
  - modern views of sources of, (76) 531
  - nitrate of silver in, (174) 142
  - progress in treatment of, (149) 346
  - salient points in epidemic of, (18) 217
  - specific treatment of, (132) 1001
  - statistics of, (10) 1699
  - surgical intervention for intestinal perforation in, (131) 863
  - treatment of, (78) 406, (90) 406, (92) 531, (126) 532, (34) 1000, (91) 1139, (74) 1205, (32) 1418, (104) 1489, (101) 1559
- Typhoid treatment of, in children, *1182
  - ulcer, perforating, (12) 1558
  - value of Widal's reaction in diagnosis of, (41) 1205
  - Widal's reaction in, (141) 1140
  - with perforation of colon and gall bladder, (14) 468
- Typho-malarial fever (133) 599, (128) 1560
- Tyrol, Curorte in, (84) 218, (69) 281

- Ulcer, corneal, (53) 141
  - gastric, and carcinoma, surgery of, (50) 1274
  - gastric, pathology of, (84) 1139
  - gastric, unusual case of, (30) 795
  - gummatous, of bladder, with abscess of prostate, (55) 281
  - hemorrhagic, partial gastrectomy for, (22) 1138
  - of duodenum considered from surgical standpoint, (37) 468
  - of stomach caused by diphtheria bacillus, (56) 406
  - perforating typhoid, recovery from, (64) 218
  - round, of stomach, (85) 1062, (18) 1418
  - tubercular, of stomach, (23) 1138
- Ulceration, chronic, of stomach, (24) 1418
  - post-typhoid, and abductor paresis of larynx, (96) 1274
  - syphilitic, (66) 1274
- Ulcerations of rectum, (150) 346
- Ulcers, corneal, (138) 282
  - few points in diagnosis of, (137) 1001
  - gastric, pathology of, (50) 345
  - of leg, (110) 63
- Uncinariosis, (3) 140
  - in man and animals in U. S., (129) 599
- Unguentum Crede, meningitis treated with, (82) 1001, (175) 1275
- U. S. Army system of personal identification, (13) 1418
- Universal medical blank, report of commission on, (120) 1633
- Upper air-tract in children, catarrhal diseases of, (52) 1559
- Urea in treatment of tuberculosis, (123) 142, (3) 861
  - quantitative determination of, (146) 863
- Uremia, acute, washing the blood in, (154) 863
  - differential diagnosis of, (4) 530
- Ureter catheterism in male, (157) 1266
  - consideration of, (64) 281
  - double, of right kidney, (93) 141
  - transplantation of, for cure of uretero-vaginal fistula, (56) 1488
  - traumatic injuries of, (62) 141
- Uretero-cystotomy, contribution to experimental, (61) 1062
- Urethra and bladder, foreign bodies in, (49) 468
  - female, carcinoma of, (86) 1700
  - gonococcal auto-reinfections of, (158) 346
  - male, stricture of, (45) 862
  - rupture of, (35) 1558
- Urethral diseases, fallacies in treatment of, *1223
  - orifice, measurement of, (161) 863
- Urethritis, acute anterior treatment of, (94) 1062
  - acute specific, treatment of, (170) 863
  - calculous nephritis and, indications for operation in, *1451
  - chronic, (111) 1139
  - neurasthenic, (74) 1632
  - or gonorrhea, (122) 1139
  - septic, remarks on, (12) 346
  - specific, (158) 470
- Urethroscope, the, (6) 1726
- Urethrotomy, internal, probable cause of failure in, (58) 1418
- Uric acid fallacies, (130) 863, (1) 1138, (113) 1206
- Uricacidemia, (139) 599

Urinary bladder, hernia of, (9) 62
  bladder, diagnosis of diseases, (5) 1631
Urination, irritable senile, (81) 1559
  prostatic obstruction to, (63) 1488
Urine, examination of, as a method of diagnosis, (136) 63
  examination, in diseases of male sexual organs, (56) 281
  freezing point of, (2) 140
  in nephritis, microscopic examination of, (94) 1489
  in pregnancy, toxicity of, (33) 1418
  suppression of, (95) 531
  toxicity of, in pregnancy, (75) 1274
Urticaria, bullous, (121) 1489
  post-diphtheritic, (26) 1138
Uterine fundus, cancer of, (72) 141
  polypi, case of, (154) 938
Uterus, cancer of, (90) 718
  cases of ventrosuspension of, (21) 598
  conservative treatment of diseases of, (169) 142, (132) 469, (110) 531
  displacements, of few etiologic factors in, (110) 1206
  fibroid tumors of, (82) 469
  hydatids of, (75) 1062
  illustrations of, (91) 218
  imparous, ridges, furrows and prominences of, (69) 406
  indications for curettage of, (95) 1419
  instrumental perforation of, (27) 1727
  labor in dislocation of, (65) 1205
  lipo-myoma of, (90) 1700
  operation for retrodisplacement of, *424
  posterior displacement of, indications for treatment of, (85) 718
  preguant, gunshot wounds of, (35) 1345, (36) 1418
  prolapse and procidentia of, (68) 406
  retrodisplacements of, (110) 1559
  retroversion of, satisfactory operation for certain cases of, *913
  rupture of, (41) 1632
  some anomalies of, (43) 1559
  suspension of, (51) 281
Uvula, primary epithelioma of, (10) 530
  traumatic affections of, *642, (58) 1000
Vaccination, (99) 63, (114) 218, (115) 531, (100) 1062, (59) 1139
  a century of, (1) 1699
Vaccination and aseptic glycerinated vaccine, (80) 346
  normal, (91) 718
  smallpox and, *1677
  technique of, (21) 1558
  vaccine production and, (4) 1699
  vexed question of, (23) 1488
Vaccine production and vaccination, (4) 1699
Vaccinia, generalized, (22) 795
  genuine, characteristics of, (19) 1558
Vagina and uterus, double, case of, (48) 62
  applied anatomy of, (111) 1700
  congenital malformation of, (24) 598
  foreign body in, (148) 1489
Vaginal drainage in non-operative cases, (147) 470
  outlet, repair of, at time of labor, (171) 863
  section for pus in pelvis, (33) 1699
Vaginitis, exfoliative, rare case of, (65) 1062
Valves of rectum, (31) 141, (48) 281
Varicella, variola and differential diagnostic points in, (115) 1062
Varicocele, (62) 1559
  suprapubic operation for, (87) 1274
Varicose veins and ulcers, treatment of, (129) 142
Variola, *307
  and varicella, differential diagnostic points in, (115) 1062
  difficulties in diagnosis of, (119) 938
Varix, filarial lymphatic, (48) 862
Vena cava, occlusion of, from compression, (4) 217
Venereal diseases, (132) 1062
  diseases, statistical study of, (82) 1559
Venesection, value of, followed by saline injection in pneumonia, (96) 1001
Ventral fixation for anterior displacements of uterus, (40) 862
  fixations, pregnancies following, (71) 345
Ventrosuspension of stump for bladder prolapse, (57) 718
  of uterus, cases of, (21) 598
Veratrum viride, (164) 63
  viride in pneumonia, (84) 1559
  viride, puerperal eclampsia treated with, (125) 532, (46) 717
Verbesserte Beinprothese, (83) 218
Vermiform appendix and appendicitis, (108) 1419
Vermin, parasitic, and other insect pests in spread of disease, (28) 1061
Version, (68) 1205
Vertebræ, cervical, dislocation of, (105) 938
  cervical, fracture of, (102) 282
Vertex, anterior, presentations, (79) 1489
  occipito-posterior positions of, (75) 346
Vesical emergencies, (3) 1558
Vicarious fovea, is theory of, erroneous, (145) 1206
Vicious circle after gastroenterostomy, (18) 468, (21) 530 530
Vienna hospitals, notes on, (3) 1345
Virchow, Rudolph, eightieth birthday of, (68) 1727
Viscera, abdominal, demonstration of model of, (7) 598
Vision, economic valuation of, (106) 346
Vital statistics in Louisiana, (143) 1140
Vitiligo, (113) 599
Vitreous phosphorous poisoning, acute, (133) 346
Voice preservation, (101) 599
Vomiting, acute, beer in, (31) 1061
  pernicious, of pregnancy, (162) 63

Water, application of, in chronic diseases, (84) 346
  importance of drinking freely of, (23) 1273
  is it necessary in cleansing of floors, (36) 658
  polluted, effects of, on fish life, (88) 346
  pollution, (93) 282
  potable, (134) 863
Wax models, preparation and uses of, (66) 862
Weak heart, cases of, (72) 62
When fortune smiles, (126) 469
While there is life there is hope, (34) 598
Whooping cough, treatment of, (128) 532, (29) 795
Widal reaction in typhoid of children, (37) 1558
  reaction, the, (141) 142
Widal's reaction, how long does it persist, (58) 1345
  reaction in typhoid, (141) 1140, (41) 1205
Windpipe, nail in, (151) 1701
Winnipeg meeting of Canadian Medical Association, (83) 1139
Winter diseases, (111) 1489
Wolff graft, large, transplantation of, (48) 1062
Woman from standpoint of life insurance, (131) 1346
Woman, medical, as teacher in medical schools, (57) 1345
  of the tenement, (155) 863, (49) 1000
  position of, during delivery, (33) 937
Woman's Hospital reports, (142) 1001, (90) 1559
Womb, retrodeviations of, (111) 1559
Women physicians in care of state insane, (93) 1062
  sterility in, (103) 938
Work and reward of physician, (103) 63
Wound, perforating, of upper lid and eyeball, (54) 1062
Wounds for sanious discharges, for, (133) 1560
  incised, (88) 1206
  penetrating, of heart, (21) 1727

Xeroderma pigmentosum, ocular affections in cases of, (49) 1062
X-ray and photographic technique, (136) 1206
  in diagnosis, (157) 142
  in diagnosis of renal stones, (31) 1205, (123) 1700
  in treatment as well as diagnosis of certain surgical diseases, (133) 1001
  stereoscope, (12) 1488
  therapeutic value of, in lupus vulgaris, (80) 1139
X-rays, cancer treated by, (23) 862
  intestinal obstruction diagnosed by, (19) 1000
  retinitis and conjunctivitis from, (8) 937
  Tesla currents and, on bacteria, *1432
  treatment of certain forms of cancer by, *688
Xanthoma of eyelids, (19) 1699

Yellow fever, experimental, (1) 217, (11) 1558
  fever, mode of transmission of infectious agent in, (27) 1273
  fever, mosquito insignificant in propagation of, (13) 468
  fever, prevention of, (26) 1273
  fever, propagation of, (7) 530
  fever, transmission of, (165) 938
  fever, two ways of transmission of, *1387
  jessamine, tincture of, in spasms, fevers, etc., (140) 346

Zygadenus frumenth and zygadenus venosus, composition of, (70) 1559

AMERICAN MEDICAL LITERATURE

INDEX OF AUTHORS

This Index includes the names of authors of articles which have appeared in this journal, as well as of those listed under Current Medical Literature. This practically includes the names of those who have published articles in all the leading journals of the country. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL.

Aaron, C. D., (16) 1061
Abbott, A. C., (62) 1345, (1) 1488
Abbott, A. W., (41) 217
Abbott, F. C., (40) 1727
Abbott, G. E., (138) 346
Abbott, L. F., (144) 1700
Abbott, L. J., (101) 1632
Abbe, R., (24) 468, (1) 1726
Abell, I., (47) 937, (118) 1419
Abrams, A., (44) 62, (55) 598, (45) 1488, (17) 1699
Abt, I. A., (40) 62, (48) 141, (65) 218, (38) 281, *445, (59) 469, (114) 1001, (80) 1489
Ackert, W. S., (24) 1273
Adami, J. G., (5) 405
Adams, A. L., (49) 1139
Adams, F. L., (89) 1206
Adams, J. H., (117) 1489, (52) 1699, (38) 1727
Adams, W. F., (97) 1139
Adamuck, E., (118) 1700
Adler, Jr., L. H., (31) 345
Adt, L. F., (82) 1418
Ager, L. C., (6) 1138
Agramonte, A., (1) 217
Aikin, J. M., (145) 346, (36) 717, (108) 1274, (7) 1726
Albertotti, G., (108) 346
Alden, C. H., (24) 217, (13) 1418
Alderton, H. A., (30) 937
Aldrich, C. J., (91) 346, (14) 405, (35) 658, (137) 1139
Alexander, S., (40) 658, (69) 937
Alexander, W. J., (38) 217, (78) 717
Alford, E. T., *834
Alger, E. M., (153) 346, (25) 468
Allaban, J. E., (81) 1700
Alleman, L. A. W., (2) 658
Allen, C. W., (72) 1205, (6) 1418, *1593
Allen, D. P., (10) 861, (2) 937, (132) 1206
Allen, L. M., (106) 1062
Allen, M. K., (46) 937, (152) 1701
Allen, S. B., (12) 937
Allen, S. E., (66) 1001
Allen, W. L., (130) 1419
Allison, C. C., (143) 346
Allison, J. E., (52) 281
Allison, W. R., (87) 141
Allport, F., (58) 531
Allport, W. H., (64) 141
Allyn, H. B., (26) 281, (14) 468, (10) 1699
Alvord, A. W., (60) 1418
Amberg, E., (85) 141, *323
Amberg, S., (69) 1488
Ambler, C. P., (147) 1063
Amyx, R. F., (28) 217
Anders, H. S., (28) 1418
Anders, J. M., (86) 62, *77, (32) 1273
Anderson, H. B., (84) 1139
Anderson, J. C., (157) 1701
Anderson, M., *90
Anderson, W. S., (9) 1000
Andrews, A. H., (128) 218
Andrews, E. W., (71) 62
Andrews, J. W., (123) 1206
Andrews, R. R., *3
Angell, G. M., (113) 469
Anthony, H. G., *104

Arbogast, B. C., (90) 1489
Archibald, F. M., (30) 217
Armstrong, E. E., (35) 1488
Armstrong, W. A., (112) 938, (76) 1205, (116) 1489, (132, 133) 1560
Arnold, H. A., (91) 1274
Aronstam, N. E., (136) 218, (43) 281, (155) 346, (61) 1345, (119) 1001, (80) 1559
Arrowsmith, H., (10) 1138
Ashburn, P. M., (34) 1632
Ashley, D. D., (55) 62
Ashmead, A. S., (117) 346, (78) 531, (62) 659, (37) 937, (126) 1062
Atherton, A. B., (42) 1559
Atkins, C., (79) 62
Atlee, L. W., (75) 862
Atkinson, A. D., (125) 346
Atkinson, J. L., (115) 1346
Atkinson, W. B., (37) 141
Atlee, L. W., (94) 141, (51) 345, (43) 598
Atwater, W. I., (25) 141
Atwater, W. O., (28) 62
Auerbach, M. A., (92) 218, (103) 531, (134) 599
Austin, A. E., (8) 598, (72) 1559
Austin, M. F., (83) 346

Babcock, R. H., (21) 217, (5) 281, (40) 531, (115) 1206, *1578
Babcock, W. W., (106) 1139
Bailey, F. R., (98) 862, (98) [illegible]
Bailey, G. L., (39) 281
Bailey, P., (8) 658
Bainbridge, W. S., (61) 62, (120) 282

Addresses.

POVERTY AND DEGENERACY: THEIR CAUSE, PREVENTION AND CURE.*

N. S. DAVIS, M.D.,
President American Medical Temperance Association.
CHICAGO.

Members of the American Medical Temperance Association: Though not retaining sufficient physical trength to be with you at your present annual meetng, I nevertheless send you cordial greeting, and ask your patient attention to the following subjects at this beginning of the twentieth century of the Christian era. During the last few months the literature of Christendom, and especially that of our own country, has been filled with eulogistic notices of the remarkable progress made in every department of literature, the sciences, arts, industries, and facilities for intercourse during the century just closed. The general correctness of these eulogistic notices, so far as they relate to discoveries in science and their practical application to improvements in every department of human industry and intercourse, is universally admitted. While it is thus freely admitted that the application of steam and electricity have made neighbors of the most distant nations, and multiplied many times the products of human industry; and the application of the facts and principles of sanitary science, evolved by our own profession, have so far limited the prevalence of epidemics and infectious diseases as to add one-third to the average duration of human life, it is very generally conceded that poverty, imbecility, epilepsy, insanity, criminality, and other diseases of degeneracy have been increasing faster than the increase of populations. So true is this that human degeneracy, both physical and mental, has become a subject of frequent discussions by sociologists, physicians and legislative assemblies, and many remedies have been suggested. As nearly all the writers on the subject allege poverty with its environments and heredity as the chief causes, so all their remedies have for their object the improvement of the first, and the prevention of transmission by the second. We are told to improve the tenement houses and ensure for them more light and air, more cleanliness and ventilation, and already millions of dollars have been expended in such work in the larger cities of this and other countries.

And to prevent the propagation of degenerates hereditarily, we are advised to prohibit by legal enactments the marriage of the feeble-minded, the epileptic and the insane, and to render impotent by surgical operations convicted criminals of both sexes. And some have even suggested that the modern care bestowed upon the defective classes in providing for them hospitals, asylums and charitable support, and for the criminals comparatively comfortable prisons, has been an important cause of their continued increase and corrupting influence upon the body politic. Careful examination will show that nearly all the remedies proposed are aimed at the removal of the effects of degeneracy instead of their causes. It is true that poverty is prone to create an environment of dirty streets; small, overcrowded and ill-ventilated houses, that favors the prevalence of typhoid fever, tuberculosis and other infectious diseases, by which the ratio of mortality is increased. But simple poverty, aided even by dirty and overcrowded tenements, has no more tendency to create either mental or physical degeneracy than do the mansions and palaces filled with all the luxuries of the rich. True degeneracy, whether mental, as manifested by the different grades of mental impairment and disorder; or physical, as seen in defects and deformities of body or limbs, or in simple defective vitality, is the result of causes capable of directly impairing the vital properties of the protoplasm and corpuscular elements of the blood and tissues of which the living body is composed: causes, therefore, that enter into the system and either remain or are repeated daily through considerable periods of time.

Consequently they do not exist in the environments of either poverty or riches. Neither are they to be found as elements of any variety of true food. Simple food, whether solid or liquid, satisfies the appetite in about the same quantity through life; and if too much is taken it produces not degeneracy, but indigestion or other temporary sickness.

There are, however, a large number of well-known substances, which, when taken into the living body in small doses, are neither digested, assimilated or used to repair the natural waste of the tissues, nor to evolve any known natural force or energy, but are soon eliminated through the various secreting or eliminating organs either unchanged or in a state of oxidation. While these substances are in the system they exert a modifying influence on the metabolic processes and functions either of particular organs or of the system as a whole, and consequently are always injurious to persons in health. If given in large doses, or in moderate doses through long periods of time, they cause tissue degenerations or even death. Therefore by chemists and toxicologists they are classed as poisons. But physicians, by using them in small doses and for brief periods of time, can and do avail themselves of their power to modify the vital processes in such manner as *to correct morbid conditions of disease, and thereby* classify them as medicines. But every intelligent physician knows that if he gives real medicine to persons in good health it only helps to make them sick, in strict accordance with the ancient proverb: "The well need not the physician, but only those who are sick." Clear and definite as are the foregoing distinctions and relations between food, poisons, and medicines, we are still compelled, even at this commencement of the twentieth century of the Christian era, to witness their confusion and practical intermixture by large portions of both the profession and the community. Thus we see on the dining tables of many in all grades of society, and still more in the social banqueting halls, not only food, but a variety of anesthetic and narcotic substances also, that the chemist calls poisons and the physician calls medicines. The substances thus used all belong to the anesthetic and narcotic classes, as opium, cocain, tobacco, ether and alcohol, all of which when taken internally either by the stomach, lungs, or hypodermically, directly diminish cerebral and nerve sensibility, muscular strength, tissue metabolism, and protoplasmic vitality in the direct proportion to the quantity used. By directly and quickly lessening the cerebral sensibility, which is man's seat of consciousness, they lessen his consciousness of all mental impressions, whether of heat, cold, pain, strength or weakness. And this is the true secret of their deceptive and destructive influence over the human race. While they thus lessen the man's ability to judge correctly, either of his own condition or of the condition of his environment, they are equally retarding and perverting the vital processes of cell growth, nutrition, disintegration and secretion, and if continued for any considerable period of time, inevitably lead to physical and mental degenerations in both parent and offspring. By the people of Asia and the East Indies opium is the chief agent used, while in Europe and America, alcohol and tobacco take precedence in all grades of society. But what is the real difference between the Chinaman's opium siesta, and the European or American's banquet of food and alcoholic drinks in an atmosphere blue with tobaco smoke; or his modern after-dinner "smoker"? As a mode of speedily getting into the land of dreams with the material world shut out, the Chinaman's method is doubtless superior.

---

* Read at the annual meeting of the American Medical Temperance Association, at St. Paul, June 6, 1901.

However, as a mode of overcoming man's sense of propriety and self-control and of materially depressing all his vital functions without actually destroying his ability to find his way home some time before the next morning, the European and American plan succeeds best. Both are deliberate indulgences in the use of subtle poisons that deteriorate health and morals in direct proportion to the quantity used.

That the daily or habitual use of alcoholic drinks, even in moderate doses, not only impairs both health and morals and leads to slow tissue degenerations, but also so impairs the metabolic and nutritive processes as to render the individual more liable to attacks of all acute infectious diseases, and more liable to die when attacked, has been fully demonstrated not only in the laboratory of the scientists, but also in every field of human labor and in every variety of climate.

The experiments of Doyen, Abbot, Ridge, Verlaguss, Ranelleti, and Goldberg, the annual reports of the registrar-general of Great Britain, and the records of life insurance companies, all prove this so completely as to leave no room for doubt or cavil. And by thus diminishing the vital resistance and promoting tissue degenerations, the alcoholic liquors equally diminish the vitality and promote both the physical and mental degeneration of their children, as was shown in a paper presented to this society, by me, in 1899. Then why longer waste time and money in efforts to renovate the tenements of the poor; in obtaining laws for securing sanitary marriages; and in devising surgical operations for rendering both degenerates and criminals incapable of extending their hereditary influence; and yet leave the causes of seven-tenths of all pauperism, crime and degeneracy that afflict the people of this country and of Europe in the form of alcoholic drinks, tobacco and other narcotic poisons, untouched or even fostered by governments for the sake of the revenue they yield? It is a striking example of economic inconsistency when municipalities and governments issue a license to sell alcoholic liquors and tobacco for a money fee, in aid of the public revenues, when the use of those same articles results in compelling the same municipalities and governments to pay out for the support of the resulting pauperism, insanity, crime and degeneracy ten dollars for every one dollar received as license fee, without counting the $2,000,000,000 paid by the consumers in our country annually without getting in return the value of a loaf of bread or of a shirt to cover their nakedness. It is more than sixty years since my mind was compelled by the inexorable rules of logic, to adopt the conclusion that if alcoholic liquors are legitimate articles of commerce and popular use, the traffic in them should be free to all, rich and poor alike; or if they are really subtle, deceptive and dangerous poisons they should be placed on the statutes of the several states with arsenic, corrosive sublimate, strychnin and other poisons, to be sold and used under the same regulations as the other articles named. It is puerile in the extreme to admit the truth of the ancient proverb that "wine is a mocker, and strong drink is raging, and whosoever is deceived thereby is not wise," and yet talk of both as stimulant, restorative and even nourishing, and to be licensed for general use. It is still more puerile to freely admit the poisonous and destructive influence of alcohol, as it exists in fermented and distilled liquors, and yet for a paltry money bribe for the public conscience, license its general use under the pretense that the influence can not be wholly suppressed, and therefore it is better to *regulate* it by a license. On the same basis licenses should be issued to a sufficient number of men to do all the stealing and murdering according to legal regulation, because both have been continued throughout the history of our race in defiance of the prohibitory laws of both God and man. The paramount question before the intelligent men and women of Christendom to-day, is not one of politics or of political parties or of social classes; but one solely pertaining to public health and morals.

It is, whether alcohol and other well-known narcotic drugs are really wholesome articles of drink or food, safe for general use; or are they absolutely subtle, deceptive and dangerous poisons, stealthily destroying both public health and morals, and constantly multiplying hereditary degenerates in all classes of human society? If the former, they are entitled to the same treatment as other articles of commerce and general use. If the latter, then their regulation belongs exclusively to the police and sanitary authorities, aided by the courts. They can not be both. That the alcohol, as it exists in fermented and distilled liquors, is a positive protoplasmic poison, directly impairing every natural structure and function of the living body in proportion to the quantity used, and the length of time its use is continued, is proved by the results of every experimental investigation concerning it, instituted by eminent scientific men, both in this country and Europe.

Their verdict is abundantly confirmed by the history and condition of the inmates of every asylum for the poor, the feeble-minded, the epileptics, the insane and the inebriates; those of every reformatory and prison; by the records of every police and criminal court; and by the details of every well-kept registry of vital statistics. As concerns danger to human life, every intelligent reader of the public press knows that the ordinary use of alcoholic liquors by persons claiming to be in health, is the direct cause of more suicides, homicides and murders every month, than is produced by all the other poisons known to toxicologists in a year. Then why not now, at the beginning of this twentieth century of the Christian era, cease calling alcoholic liquors stimulants or restoratives, and not only speak of them as subtle and dangerous poisons in every household, but also concentrate all the facts of science, clinical experience, and of economic and criminal records, in favor of having alcohol and all liquids containing 2 per cent. or more of it, placed on the statutes of the several states along with arsenic, strychnin, etc., to be sold and used under the same regulations and penalties as other poisons dangerous to the public health and morals? If this were accomplished it would soon remove one of the chief corrupting influences from the field of politics, and place it under the domain of the police and health authorities, aided by the courts, where it legitimately belongs. And it would do more to prevent tuberculosis and all forms of human degeneracy than all the other measures combined.

SECTION ON STOMATOLOGY.

ADDRESS OF CHAIRMAN DELIVERED AT THE FIFTY-SECOND ANNUAL MEETING OF THE A. M. A., HELD AT ST. PAUL, MINN., JUNE 4-7, 1901.

R. R. ANDREWS, A.M., D.D.S.

CAMBRIDGE, MASS.

For the second time you have honored me by making me your chairman. I appreciate the courtesy and kindly feeling which has prompted this action, and thank you for it. In reviewing some of the more important matters which have been presented to our profession during the past year, it seems to me that the symposium on dental education presented before this Section at its last meeting is one of considerable importance as an educational factor. The time was ripe for such a discussion, and we are already beginning to see its good results. At the beginning of this twentieth century we find that advanced conditions call for a higher educational and professional standard. Some of our schools are already recognizing this, and have decided that another year should be added to their course of study, making it of four years, and they also have under consideration the requirement of a degree in letters, or its equivalent, for entrance to their schools. Necessity for such action arises from the fact that this is an age of progression; the material development and enterprise of the time is irresistible. The man who would succeed in a profession must now grasp every legitimate opportunity. His equipment should be larger and his education broader than formerly. Success in the future is to come to him who shall be educated to do a thing as well as it is possible to do it; that is, he must become a specialist in some department of his chosen profession. I have been informed that President Eliot, of Harvard University, after reading the symposium on dental education, writes to our Secretary that he is favorable to the establishment of a medical university where all the medical specialties, including dentistry, shall be taught under one head, and that a common degree shall be given to all. President Capen, of Tufts College, writes me under date of February 21, 1901: "I have received your pamphlet containing an account of the proceedings of the Section on Stomatology of the AMERICAN MEDICAL ASSOCIATION. I have read not only your own paper with great interest and profit, but have examined the other papers sufficiently to get the drift of the sentiment of the Association. I was surprised to find it so strongly in accord with my own views. I may add that I find now, both in our medical and dental faculties, an opinion strongly favoring a four years' course for dental students, as well as medical students, and the common degree of M.D. for all.

Some of the criticisms against this common degree come from eminent professors in our special schools, who are earnest, able and conscientious men, sincerely believing that if we are to educate our students in medicine, they will become theorists, as are most of the educated dentists from the schools of Europe; and that the practical technical training, which in the past has made the name of the American dentist honored all over the world, will no longer be acquired; that under this new system American dentists will become thinkers rather than operators, scientists rather than practical men.

Such opinions are to be respected, but, on the other hand, the four years' course could be systematically arranged to give the technical training fully equal to that given to-day in our best special schools, together with the necessary medical education that shall warrant the common degree. We should demand the same medical education that is required in other medical specialties, with all, or more, of the practical training that shall teach the hand as well as the head. Such a system has never yet been tried, but it is reasonable to suppose that two men, being equal otherwise, the one with this advanced education must necessarily be the broader man, and the profession must necessarily be benefited by such a training.

Another subject nearly as important is in relation to the many problems now before our profession, and as to the best methods of solving them. This has recently been considered by the Dental Society of the State of New York, and should receive our cordial coöperation. In considering these problems, will it be wisest to have the individual investigator proceed in his own way, paying his own expenses in solving our problems, or will it be better for national or state societies to establish commissions, whose duty shall be to oversee and encourage research work, propose problems to be worked out, and also have it in their power to furnish the necessary funds for carrying out this work? If such a commission were established, is it not reasonable to suppose that the profession would be greatly benefited, and result in a more uniform practice? Such a commission should be composed, not merely of eminent practitioners, but of men of judicial minds and training, whose duty should be to collect the facts, weigh the evidence, and give rulings on disputed points.

Among the students in our special schools there are always to be found a few who have the inborn faculty of investigation. While building up a practice they give a very considerable amount of time in solving some of the scientific problems which appeal to them. Some of these men become well known to the profession, others do not. There is a very considerable expense attending many of these investigations, and research work would be better done if they could afford suitable apparatus. Work of this nature is of value to the whole profession, and it seems as though it would be wise to establish the commission suggested. Investigators could then devote a certain portion of time to solving problems, and receiving therefor adequate compensation. Our schools also should encourage research work, and a department for it should be established, where men who are capable should be given the opportunity to work along lines congenial to them. This may lead to a career of much value to themselves and of great good to their profession.

There are one or two important matters which I think would be wise to consider in regard to the subject of State Boards of Dental Examiners, which is to be presented in a series of papers for our consideration and discussion at this session. This subject is an important one, and will, I am sure, receive careful attention in broad and generous criticism. We are all mindful of the fact that in many of the states the Board of Dental Examiners has been largely instrumental in raising the professional standard and of influencing in no small degree the necessity for a higher educational qualification in our special schools. With all this there is yet something to be desired. An appointment to the board should never be a political gift. The nomination of suitable persons to fill vacancies on such a board should be made to the appointing power by nominating committees from the state societies elected for this purpose. This plan works admirably in Massachusetts. A standard should be established by the National Board of Dental Registration for the boards of the different states, that shall make it possible for a person who has once passed a successful examination to practice his profession in any other state, without further examination. And again, in justice to the older members of our profession, discretionary powers should be given the boards of the several states to guide them in granting certificates to those who have for years been active in honorable practice, and who are not, by reason of advancing years, fitted to pass the same examination as should be demanded of recent graduates.

In the department of prophylaxis the future is bright with possibilities. Recent investigation is opening up a field that gives promise soon of successful treatment. J. Leon Williams, in his brilliant paper on "The Bacteria of the Human Mouth," has demonstrated beyond a doubt that there exists upon the teeth of persons predisposed to caries, a hardened gelatinous film, which is a culture medium for the growth of myriads of microorganisms. This film he calls the gelatinous microbic plaque. The organisms found here are largely the leptothrix racemosus, together with the leptothrix buccalis. The leptothrix racemosus is, like the leptothrix buccalis, a thread-like form, but differs in having myriads of spores growing from an extremity, where they multiply with marvelous rapidity. They are benign or malignant, according to their environment, and the saliva in an abnormal condition is the exciting cause of dental caries.

Prof. J. P. Michaels, of Paris, who has given the results of his recent brilliant investigations of human saliva at the International Dental Congress, tells us that, as a result of over-activity of the liver, a superabundance of glycogen may be found in the saliva, giving it an alkaline reaction; but upon coming in contact with the ptyalin, which is always present in the saliva, a reduction occurs of the glycogen, first to glucose and then to lactic acid, which unites with the lime of the tooth. He has experimented with ptyalin and glycogen (either alone giving a neutral solution) and put them in separate bottles containing distilled water, then connected the liquids in the two bottles by a piece of cord, which formed a loop around, and in contact with, a chalk crayon. By capillarity the liquids came together at the chalk, which dissolved away wherever touched by the cord. He asks: "Does not this tend to show how decay of the teeth may occur even in an alkaline saliva, and independent of microbic influences?"

Michaels has also shown that exciting and pathological conditions can be found, and are positively recognizable in the saliva. He has been able to determine the histochemical condition of saliva of those who are not affected with carious teeth, and suggests that nutrition may establish vital conditions so desirable in securing immunity from decay.

A paper of special interest on treatment to prevent the decay of the teeth has been presented by Dr. D. D. Smith, of Philadelphia, and should command our serious attention, when considered from the standpoint of recent investigation. The simple method is to place in a suitable carrier a piece of orange-wood sharpened to a chisel point for using on the flat surfaces of the teeth, and another shaped to a pencil point to be used between them. These points are to be renewed as often as they become frayed. Before using they are dipped in water and then in pumice, and with them the surfaces of the teeth are polished well up into the festooning of the gum, using enough force to stimulate, and cleansing what may appear to be clean teeth, going over all surfaces thoroughly, outside, inside, between, and on the occlusal surfaces. This work should be done as thoroughly as it is possible to do it, leaving the teeth in a polished and smooth condition. Such action has a stimulating influence, and under this stimulation the internal vital function seems roused to new activities. Treatment is to be given once a month, the patients are instructed to thoroughly care for their teeth daily, using fine salt once a week. It produces stimulation of the gum tissue, of the alveolar tissue, and of the whole oral structure. This simple, but vigorous, treatment, by removing the gelatinous microbic plaque which Williams describes, induces the most attractive and apparently most perfect condition of the mouth attainable.

Another subject of particular interest to this body is the law creating a dental service in the United States Army, and enacted by Congress since our last session. Although the law, as enacted, is not all that we asked for, it is an entering wedge which may result in more satisfactory legislation in the future. Dr. Maynard, of Washington, somewhere about the year 1850, was very considerably interested in the enactment of such a law, and used his influence with the President and Secretary of War to have it passed, but without success. In July, 1858, the late Dr. H. J. McKellops, of St. Louis, offered a resolution, with the idea of establishing such a law, before the Western Dental Society, at Quincy, Ill. It may thus be seen that the movement is not a new one, but that, with the growth of public appreciation of dental services, which is justly regarded as one of the common necessities of life, the demand has been created and recognized. Dr. John S. Marshall, of Chicago, one of our most esteemed and valued members, has been appointed President of the Examining Board of Dental Surgeons of the United States Army. He is a man in every way eminently fitted for this position. The high standard which is demanded for the appointment of contract dental surgeons under the new law may be recognized from the fact that out of fourteen candidates only two successfully passed the examinations. Dr. Marshall, in a communication, says: "It is to be hoped, therefore, that our dental schools will not recommend any young men to come before this board who are not thoroughly well qualified, theoretically and practically, in all the branches comprising the curriculum of our best dental schools."

In the department of biology, science has made some of her most remarkable advances. The work of the investigator has opened up new vistas of relations, of which many of us have never dreamed. In an article entitled "Aspects of Recent Biological Research," recently published in the International Monthly, from which my allotted time will allow only the very briefest quotations, Prof. E. B. Wilson, of Columbia University, says: "Chemical analysis proves that protoplasm is not a single chemical substance, but a highly complex mixture of many highly complex organic compounds, which undergo continual chemical transformations—indeed, a living cell is doubtless the area of the most complex chemical operations taking place in nature. . . . . In the fertilization of the egg, a single cell derived from the father (the spermatozoön) unites with a single cell (the egg) derived from the mother, while the paternal nucleus unites with the maternal. By continued division of the single cell thus formed, arise all the cells of the body. If now we examine the details of this process, we find one remarkable difference between the egg and spermatozoön, namely, that while the two contribute equally to the nucleus of the fertilized germ, the whole, or very nearly the whole, of the remaining cell substance (protoplasm) is supplied by the egg. We have thus a substantial basis for the conclusion that the protoplasm of the embryo is derived wholly or mainly from the mother, while the nuclei are equally divided from both parents. If this result be placed beside those derived from microscopical vivisection, we gain for the first time a clear, if superficial, view of the mechanism of inheritance, and can form a definite mental picture of the manner in which it is effected. As the paternal and maternal nuclei approach each other within the egg, each undergoes a complicated metamorphosis, and finally resolves itself into a number of rod-like or worm-like bodies known as chromosomes, which are exactly equal in number and similar in form in the two. At this period, therefore, the egg no longer contains two nuclei, but in their place two precisely similar groups of chromosomes, which are respectively paternal and maternal in origin. As the egg undergoes its first division to form the first two cells of the embryo, every chromosome in each group splits lengthwise into two exactly similar halves, which separate and pass, one to each of the daughter cells. Each of the latter, therefore, receives two similar groups of daughter chromosomes, paternal and maternal, which are exactly reduplicated in the other cells; and from these two groups, in each cell is built up a daughter nucleus, shown by its mode of origin to be equally derived from both parents. At the second division, the chromosomes reappear, again split lengthwise, and the halves are again equally distributed to the daughter nuclei, and so on throughout the entire life of the animal."

Among other facts noted in this article by Prof. Wilson is the following: "The egg may be fertilized by chemical stimulus, without participation of the male element. If, for example, the eggs of sea-urchins be allowed to develop in sea water containing a very slight excess of potassic chlorid, the development of the embryo is greatly altered, no skeleton is formed, and a larva results which, though living and vigorous, is of widely different form from the normal ones. If, in place of potassic chlorid, lithium chlorid be added to the water, the changes are still more remarkable, the embryo never infolding the cells which normally give rise to the alimentary canal, but developing, as it were, inside out. These monstrous forms are, of course, incapable of nourishing themselves, and ultimately perish; but the result is of high interest, as opening the possibility of creating wholly new organic forms by varying slightly the conditions of development. . . . Certainly new growths of the highest interest, relating to the chemical conditions in the living matter, may be looked for along the lines of research thus opened. . . . Experiments on insects, frogs, and rotifers have already given good ground for the conclusion that sex is in these cases determined by conditions of nutrition, which again in the long run are reducible to chemical conditions. The possibility is thus opened that we may yet succeed, not only in fertilizing the egg by chemical means, but also in rendering the organism male or female, by analogous methods."

In closing, I regret that I have not been able to offer any research work, and that the time allotted for this address will not permit the review of many important papers offered to the profession during the last year. I would suggest that the leading symposium for our next year's session be "Prophylaxis." Our section is well fitted to consider this subject, and the recent investigations should stimulate us to earnest and serious work.

Original Articles.

THE APPOINTMENT OF STATE BOARDS OF MEDICAL AND DENTAL EXAMINERS.*

WILLIAM CARR, M.D.
NEW YORK CITY.

Not many years ago it seemed to the majority, as it now seems to some of those interested in the advancement of medical and dental education, that diplomas from chartered colleges or schools gave sufficient assurance that their possessors were qualified to practice in the general or special fields of medicine in which degrees had been conferred upon them, and that the diplomas granted served as an adequate standard for license. This view assumed that instruction in such schools was faithfully given, by competent teachers, during a period of sufficient length to qualify students for the commencement of their careers, and also assumed that diplomas were conferred only upon those who, at the completion of such a period of study, had demonstrated, upon examination, their qualifications. It also assumed that charters would not be recklessly granted to professional schools, and that such charters would be revoked upon proof of their abuse. Experience has demonstrated the fallaciousness of such assumptions. Legislatures have passed incorporating acts most improvidently. So-called colleges have been created at the solicitation of charlatans having no other purpose in view than the manufacture and sale of parchments conferring degrees *in absentia,* without any safeguard or state supervision. The Buchanan and Delavan diplomas are fair types of the product of these factories, which became a stench in the nostrils of decent men.

An attempt was made to remedy this evil, so far as it affected medical license in the State of New York, by a provision requiring that diplomas granted outside the state should be endorsed by our own schools. But this plan proved of little avail. Not only did respectable colleges endorse fraudulent and valueless papers, but the diploma business was carried on by certain of our native corporations.

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

It therefore became necessary to do away altogether with the diploma standard, for the reason that it could not be higher than that of the poorest institution authorized to confer a degree.

The plan of creating State Examination Boards, with power to supervise licenses, next suggested itself. To-day such boards exist in nearly all of the states and territories, but with varying powers and standards, which will be found set forth in detail in the carefully prepared bulletins issued by the University of the State of New York, and in the publications of the National Bureau of Education.

At the commencement of the experiment it seemed to those resorting to the plan that to empower these boards to list the "reputable" schools and to accord to their diplomas only the licensing power, would meet the needs of the situation. In many jurisdictions such listing is still the chief function of the state board, and diplomas of the colleges classified as reputable afford therein a license to practice. But this plan has not proved successful, and the refusal of state boards to list certain of the so-called colleges has given rise to no small amount of litigation, especially in the West, where the right of a state board to exclude graduates of schools refused listing by the board has been vigorously attacked in mandamus proceedings.

In twenty-three states, however, the diplomas of even the best schools no longer afford a license to those upon whom they are conferred, but only serve as one of the qualifications of candidates for examination before state boards. This separation of the licensing power from the diploma has proved beneficial to the really reputable schools, some of whom strenuously opposed it. When the diploma constituted a license, faculties seem to have been swayed, insensibly perhaps, by a feeling that the payment of fees on the part of a student, especially if he were somewhat diligent, established a contract right on his part to receive collegiate authority to practice upon the public, and, as a consequence, the standard of education was low, compared with the standard of today. With the abolition of this right to license, which was an apparent, not a real, privilege, the value of a diploma was presently perceived to be proportionate to the reputation of the institution conferring it, which, in turn, was incited by self-interest as well as love of scholarship, to raise its standard and confer its degree only upon those earning it. The period of study has been extended, and if the medical and dental laws have accomplished no other result than the raising of college standards, they find in that alone their ample justification.

The examination of candidates for license being vested in a state board, it is of the first importance that such a body should be properly constituted. In the first place, it goes without saying that its members should not only be honest and competent, but independent of extraneous influences, and with eyes single to the performance of their sole duty, namely, the admission to the profession of men competent to practice, and the exclusion of incompetents from its ranks. In order to command respect and authority, it is equally clear that the board should be composed of men of standing in the community and in their profession. Its members should be abreast of the science of the day in its application to their calling, for the rule of liability in malpractice cases takes into consideration the advanced state of science. Without being identified with teaching bodies, these examiners should be conversant with the arts of instruction and examination, able to frame questions of a nature to elicit the candidate's knowledge, and ascertain his ability to apply it. Unless the minds of the examiners and of the examined meet; unless each understands the other's aim, examinations are fruitless, impediments rather than aids.

Again, the office of examiner should be, and is, when proper tests are regarded in filling it, a post of honor. For that very reason, it should never be filled by one whose appointment is not made because of his competency to perform the duty with which he is to be charged, but for the sake of conferring honor upon the incumbent. It is but natural that the post should be sought for the honor it confers, and yet a conscientious man, apprehending and purposing to perform faithfully its duties, will be slow to seek it. The position of an examiner upon a negligent or incompetent board is the reverse of honorable, and no man of professional pride and standing would suffer himself to be appointed to such a body.

Unhappily, there have been instances of late—let us be thankful that they did not occur, and could not have occurred under the system adopted in the State of New York—of the appointment for personal and political reasons of conspicuously unfit boards. These appointments have been made through the heads of political divisions of the country, and it is but fair to presume that the successful candidates sought the places rather through political influence than by demonstration of their own fitness.

In our State of New York such scandals are not possible. I do not say this to praise our own state board, or to claim for it especial excellence on account of the individuals who compose it. To do so would merely be an exhibition of bad taste, and I certainly have no desire to underestimate the many excellent, able and learned men who honor the examining boards of other states. But what I mean to say is, that those very men are wronged and handicapped when the appointing power, for political reasons, associates them with men of lesser qualifications, and this is what has happened elsewhere, but can not happen in the State of New York, for the following reasons.

The University of the State of New York is not a teaching body, nor yet a political body, but is created for purposes of examination and supervision. It has been assailed and criticized from time to time by politicians who would abolish it, and thereby make way for some substitute which would afford patronage, through themselves. Fortunately, such efforts have hitherto failed, and whatever other criticism may have been made upon the Board of Regents, we have yet to hear any one suggest that its actions have been animated by political or partisan motives.

I sincerely hope that the day is not far distant when each state will have a board of regents, possessing the powers of the Regents of the University of the State of New York, or, as suggested by President Henry Wade Rogers, that "there should be established in each state a council of education, which should be invested with powers similar to those of the Regents of the University of the State of New York, and it should be composed of the most eminent men of the state, without any reference to political considerations. No degree-conferring power or no degree-conferring institution should be incorporated without the approval of the Council of Education."

If such a condition could be made National there would be no further cause for criticism by foreign nations, who now claim that the degree-conferring power in America is without proper supervision.

With the University lies the power of appointing our boards of medical and dental examiners, from candidates nominated by the state societies. The dental board is divided into four classes, the term of one class expiring on July 31 in each year. Prior to the second Tuesday in June of each year, the state society is empowered to nominate from its membership twice as many candidates for filling vacancies to occur on the board as there shall be such vacancies, and from these nominees the regents appoint.

Thus it is sought not only to remove the constitution of our examining board from state politics, but to take it out of professional politics. The state society, the purpose of whose incorporation is to assemble together men to whom the interest of the profession, its advancement and honor are dear, and membership in which is open to all who are of good standing in the profession and chosen from their districts as representative men, has power to say to the regents: "We submit to you the following names of men who, in the opinion of the dental profession throughout the state, are fit and worthy to represent it. But we can not appoint, we can not by intrigue constitute the board; that must be done by the regents, and with them rests the responsibility for ill-advised selection, limited only by our responsibility in submitting poor material for their choice." Thus there is a double responsibility created; we are responsible for our nominees, and the regents for their appointments, and thus it is that we have removed, so far as human ingenuity could do so, the constitution of our board from the hands of the politicians; and, if I have spoken of our system of licensing dentists as good, I have still spoken less strongly than Dr. Allen, secretary of the advisory committee of the National Association of Dental Faculties, who, writing under date of Nov. 15, 1899, for "A Comprehensive Report from the New York Examiners," was kind enough to say of the body to which he belonged, "the entire committee regard the New York Dental Law as the best in the country."[1]

Before the board thus constituted come the candidates for license, after satisfying the board of regents that they have been graduated from the professional schools after receiving the proper preliminary education. But the examiners do not know the candidates who appear before them or the schools from which they come. To guard against any possible favoritism candidates are examined by number, and it has even happened that men have appeared before the board who have slipped by the outposts and have passed the professional examination without having satisfied the preliminary requirements, with the result that their success in passing the state board has yet failed to license them to practice within the State of New York, by reason of their failure to comply with the preliminary requirements.

The success of our system, therefore, depends upon the existence in the State of New York of our University, which, while controlling all educating bodies, does not itself possess a teaching faculty; thereby have we been able to keep our board out of politics and have been able to create a double responsibility for its appointments.

That we have excluded from the profession all incompetents would be claiming to be something more than human; what we can safely maintain, however, is that we have guarded the entrance to the profession, not only with sentinels, but with watchmen over the sentinels.

REVENUE FOR CONDUCTING THE WORK OF STATE BOARDS OF DENTAL EXAMINERS.*

GEO. L. PARMELE, M.D.

HARTFORD, CONN.

In this "Symposium on State Boards of Dental Examiners in Their Relations to the Profession and the Colleges," I am asked to deal simply with the subdivision: How Shall the Revenue for Conducting the Work of the Boards of Examiners Be Obtained? 1. By taxation of the people? 2. By fees from the candidates? 3. By taxation of the profession?

Naturally our first inquiry would be as to the causes bringing about dental legislation, and the purpose of such laws.

The majority of the dental world labor under the idea that these dental laws were passed to protect the dentist from the dentist; that is, to bar out the dental parlor man and admit to practice only those who will live up to the code of ethics, but notwithstanding the fact that more or less selfishness on the part of the dental profession prompted their advocacy of such enactments, the laws are for the safety and welfare of the people. This being the case, you say, let the people pay.

No doubt there are many good reasons why the people should pay; for example, were the people taxed, then many worthy, but financially embarrassed young candidates, who have expended at college their last hard-earned dollar, would not be required to wait until they could earn enough to satisfy the demands of the state boards, although I think all candidates would be better off if they would serve as assistants with some successful practitioner. There they would gain experience, not only in the manipulation necessary to the care of the dental organs, but learn, what is vastly of more importance to them at the outset, how to deal with people and to meet the many petty but important details of daily routine in a successful professional office. Were there no other objection to the people being taxed and the state paying these expenses, the fact confronts us that in most states it would be impossible to obtain adequate legislation for such expenditure, from the fact that the average legislator, on account of his peculiar ideas concerning false economy, in appropriating state funds, would never vote for such expenditure, when he was confronted with the fact that in every other walk of life he who dances pays the fiddler. It would be waste of time to deal further with Subdivision 1.

Let us leave Subdivision 2, "fees from the candidate," while we quickly dispose of Subdivision 3, "taxation of the profession."

In our professional ranks there are many generous, whole-souled, self-sacrificing men, but when we talk of securing the revenue by taxing the profession it means the whole profession, and judging from my own experience with the average dentist it would be a greater task to get the dental profession to allow itself to be taxed, so that other dentists might enter into competition with them, than it would be to get the people, the free and enlightened voter, to submit to taxation in order that another voter might carry on his business.

[1] Regents' Bulletin 9, February, 1900, Dentistry, p. 751, Note.

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

This brings us to the only other source of revenue, 2, "the candidate."

When I was requested to prepare this paper there came upon me a sudden elation, for it seemed that for once I knew where to go for the desired information.

In a chat with a lawyer along the lines of dental legislation, he gave me the impression that the state should pay the costs of examination, but alas, when I hastened to him, note-book in hand, I found that I had misunderstood his remarks. Our talk had been of a certain retroactive clause in a proposed dental bill, and that which he had intended to say was, that if this bill should pass it would be a hardship to compel certain ones to pay a second fee, and in justice the state in this case should be responsible.

Continuing the conversation after I had stated the question I was to deal with, the attorney assured me that so far as he was informed of the various license-granting powers, there could be but one answer to the question. Later investigation has convinced me of the soundness of his opinion.

In the work of various other boards, for example, health, forestry, and fisheries, the expenses justly come from the public funds, as the benefit is not for individuals, but for the people; but in the case of a license to carry on some trade or profession, whereby an individual is allowed certain privileges, the individual should pay *the costs, notwithstanding the fact that the laws governing* such cases are enacted for public protection.

Let us glance for a moment along the various walks in life where licenses are required before one can enter the ranks, and see by actual reference to a few state laws, from what source the revenue is obtained: Georgia, state board of embalmers, license $5, from the candidate; Ohio, physicians, dentists and druggists, fee $25, from the candidate; South Carolina, homeopathic board, fee $5, from the candidate; New Hampshire, plumbers, fee $1. for examination, 50 cents every year, from the candidate; Virginia, medicine and surgery, fee $10, from the candidate; Nebraska, barbers, examination $1, and annually $1, from the candidate; Michigan, barbers, examination $5, and annually 50 cents, from the candidate; barbers in business at passage of law, $1, and annually 50 cents, from the candidate; Tennessee, osteopathy, fee from candidate for recording diploma from one named college, $1, and all not so recorded, fine $100.

This list could be continued indefinitely, and would still have the refrain, "from the candidate."

"Where the successful prosecution of a calling requires a certain amount of technical knowledge and professional skill, and the lack of them in the practitioner will result in material damage to the one who employs him, it is a legitimate exercise of police power to prohibit any one from engaging in the calling who has not previously been examined by the lawfully constituted authority and received a certificate in testimony of his qualification to practice the profession." "It is the common custom in all the towns and cities of the United States to require the payment of a certain sum of money as a license fee, for the privilege of prosecuting one's profession or calling. The license is required indiscriminately of all kinds of occupations, whatever may be their character, whether harmful or innocent, whether the license is required for the protection of the public or not. . . . It is either a license, strictly so-called, imposed in the exercise of the ordinary police power of the state, or it is a tax laid in the exercise of the power of taxation. In many cases it becomes exceedingly important to determine under which power the particular license is imposed. For example, if the license is a tax, the bill must originate in the House of Representatives, according to the almost universal requirements of constitutional law. But if it is a *police regulation*, the bill providing for it is constitutional in whichever house it was introduced." "*It is one of the 'ways and means' of defraying current expenses.*"[1] A license tax has been held to be reasonable when imposed upon vendors of milk, hucksters, pedlars, vendors of cigarettes, upon attorneys, physicians, bankers, hacks and drays and other vehicles. So likewise may such tax be exacted of keepers of places of amusement, of dealers in second-hand articles, pawnshops, insurance brokers, auctioneers. In short, the state has the power to impose a license fee as a tax or a police license upon every kind of business.

"*In the regulation of all such occupations, it is constitutional to require those who apply for a license to pay a reasonable sum to defray the expenses of issuing the license, and what is a reasonable sum must be determined by the facts in the case.*"

"*When a municipal corporation is given the power to license useful trades or occupations, it can not use the license as a tax to raise revenue, nor is it authorized to entirely prohibit the exercise of the trade or occupation* by any excessive license fee."[2] Mr. Justice *Manning* says:

"A proper license tax is not a tax at all *within the meaning of the Constitution* or even within the ordinary signification of the word, tax. . . . The imposition of a license tax is in the nature of the sale of a benefit, or privilege to the party who would not otherwise be entitled to the same. The imposition of an ordinary tax is in the nature of the requisition of a contribution from that which the party taxed already *rightfully* possesses."

I have examined all state laws concerning dentistry, numerous other laws and legal authorities, and so far I have not succeeded in finding a single case where the costs did not fall upon the applicant, therefore in answer to the query: How shall the revenue for conducting the work of the state boards be obtained? I reply: From the candidate.

REVENUE FOR CONDUCTING THE WORK OF BOARDS OF DENTAL EXAMINERS.*

V. E. TURNER, D.D.S.
RALEIGH, N. C.

BY TAXATION OF THE PEOPLE.

Although one of the main objects of examining persons wishing to commence the practice is to secure protection for the people from inferior dental service, and it would seem for such immunity the people should be taxed as they are for any other protection which the law affords. This is doubtless the correct principle, as the members of the state boards are state officers, it would seem most rational that they should be paid as other state officers.

But there would be great difficulty in influencing legislation, as any proposed enactment relating to dental surgery or any branch of medicine, which carried with it a draft upon the treasury of a state, would excite the opposition of the average legislator. It would not be expedient to ask this, as it would be fatal to any further amendment to our present dental laws. In fact, in some of the states, it is specially provided that under no circumstances shall these dental enactments be of any expense to the state.

BY FEES FROM THE EXAMINATION OF CANDIDATES.

All things considered, the most satisfactory plan of securing compensation for the service rendered by members of the state examining boards should be derived from the fees received from the applicants for license. All legislation prescribing and controlling the standard of qualifications of licentiates in dental surgery has been effected through the influence of state dental societies, and every one will concede that such enactments are of great benefit not only to the public but to all reputable practitioners in maintaining a higher standard of professional attainments, which gives more dignity and a higher consideration among the other professions as well as the public.

It is for these reasons, to a great extent, that it is most earnestly desired that the incompetent and unworthy should be excluded from the practice.

The amount of compensation should be to some extent commensurate with a reasonable expectation of income to be derived from these fees. Of course, in some states it would be larger than in others, but a per diem of $10 or $15 and 3 cents mileage would not be extravagant remuneration for members of examining boards, except the secretary, who should be paid $25 per annum additional.

If these and such other legitimate expenses should aggregate less than the amount of fees received, the balance should be turned over to the state society for conducting scientific research or other educational purposes. If these amounts should aggregate more than the fees, then the state society should supply the deficit. It should not be asked of any competent practitioner to attend these meetings and make these examinations for less compensation than the amount mentioned.

In addition to these duties, each member must prepare suitable question lists before the meeting and examine the replies after, in order to give the proper grading to each applicant examined, and both of these require the exercise of much thought and judgment.

BY TAXATION OF THE PROFESSION.

If this should be necessary, then the profession should not hesitate to bear that burden for the sake of the benefit which is derived from a proper discrimination between the worthy and qualified and the unworthy and incompetent; and in order to prevent the lowering of the standards of professional equipment and to provide against the advent of those who pursue the calling as a hustling business rather than a learned and dignified profession.

Hydrotherapy Without Water or Cold.—Winternitz, the professor of hydrotherapy at Vienna, states that in the local application of alcohol compresses we have an effective hydrotherapy without water and without cold. First introduced by Salzwedel for phlegmonous inflammations of the skin, Winternitz has found them extremely beneficial in herpes zoster, in the gangrenous as well as the hemorrhagic form. The pain vanishes almost immediately after the application of the alcohol, and the process arrested and cured. The compress is made of six to eight layers of absorbent gauze dipped in 65 per cent. alcohol, covered air tight and left for twenty-four hours.

THE DENTAL COLLEGE STANDARD.*

1. IS IT WHAT IT SHOULD BE? 2. IF NOT, WHAT IMPROVEMENTS SHOULD BE MADE? 3. HOW MAY THE REQUIREMENTS BE IMPROVED?

CHAS. C. CHITTENDEN, D.D.S.
MADISON, WIS.

In order to intelligently consider the subject in hand it will be well to first define, if possible, what is the dental college educational standard as at present accepted in this country.

Much agitation and discussion of the subject has for the past two or three years occupied the attention of the journals and the various dental societies, from the national bodies down to the smaller local organizations, as to what the standard should be, but the average practitioner would be at a loss to define what the present situation is if asked to do so. The fact is the whole matter is in a state of evolution just now, the general trend and consensus of opinion seeming to be that high school graduation is the probable goal within the next few years. The fact also is that until 1899 there never was any established standard in this country, each school being a law unto itself as to whom it should matriculate and graduate. The National Examiners sought for years to induce National Faculties to establish a minimum standard as a basis from which to go forward, but it was not until an open rupture, based on a standard demanded by the Examiners as a criterion of reputability and recommendation of schools to the various boards, brought the two national bodies together at Niagara Falls in 1899 in a conference which resulted in the following code of rules being placed on the records of the Faculties Association:

"The minimum preliminary educational requirement of colleges of the association, for the session of 1899-1900, shall be a certificate of entrance into the second year of a high school, or its equivalent, the preliminary examination to be placed in the hands of any state or county superintendent of public instruction."

Amended Rule VIII. National Association Dental Examiners, Sec. 2.—"The following preliminary examination shall be required of students seeking admission to colleges recommended by this association: The minimum preliminary educational requirements of colleges of this association for the session of 1900-1901 shall be certificate of entrance in the second year of a high school, or its equivalent; the preliminary examination to be placed in the hands of the State Superintendent of Public Instruction, as adopted by the State Board of Missouri."

Also, "the minimum preliminary educational requirement of the colleges of this Association, beginning with the session of the year 1902-1903, shall be a certificate of entrance into the third year of high school, or its equivalent. The preliminary examination to be placed in the hands of the State Superintendent of Public Instruction. Nothing in this rule shall be construed to interfere with colleges of this association that are able to maintain a higher standard of preliminary education."

The above represents the exact situation at this time, to-wit: present standard, one year of high school, promised standard for 1902, two years of high school, with the agreement between the two bodies that all schools belonging to the National Association of Dental Faculties and living up to its standards and requirements as laid down, shall be accepted as reputable by the examiners and recommended to the various state boards for recognition. The regents of Michigan, under the advice of the venerable dean, Jonathan Taft (to whom be all honor), took the initiative in setting the pace and required high school graduation for 1900. The regents of New York will, in 1902, culminate a progressive advance in requirements to full high school standard. At the World's Dental Congress in Paris last summer high school graduation was made the international standard for entering dental colleges. So it would seem quite certain that, viewed at large, high school graduation is accepted as our *Ultima Thule.*

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

The National Association of Dental Faculties is a body composed of the membership of 51 dental schools, all of which accept and agree to conform to the regulations and rules formulated by that body in the conduct of their schools. However much these schools may vary in their equipment, faculty and general effectiveness as educational institutions, yet, as long as they retain membership in that body, all, by special agreement with the examiners, command the same privileges and recognition, subject to the various dental laws in nearly all the states—membership in that body now being accepted by all state boards as the criterion of reputability before the law. This association, backed at all times by the National Association of Dental Examiners in its every forward move, has in the eighteen years of its existence wrought wonders in the development and unification of curricula, the evolution of dental technics, lengthening course of study and special training, and in a hundred ways making the advantages offered for obtaining a complete dental education and equipment almost ideal; so that the student who comes to the dental college to-day prepared and fitted to assimilate and appropriate what may be his own for the mere taking—has no excuse for leaving school unprepared to enter successfully on the practice of dentistry.

The code of rules and standing resolutions formulated by this association for the government of its members in the conduct of their schools is a monument of sense, wisdom and ethics which would redound to the credit of any deliberative body of men having the interest of their calling at heart—and yet strange to say, never, through all the years of its existence has it seemed to occur to it to effectively inaugurate and establish any given educational preparation as a minimum standard requirement for entering the dental college course—until the regulation of one year of high school above quoted was adopted, and that only after the demonstration of much friction on the subject between the examiners and faculties. The query arises naturally why this important subject was so long ignored. But one logical answer suggests itself, namely: The different schools, or at least a majority of them, preferred to retain in their own hands the decision, without dictation from any source, as to the fitness of an applicant for matriculation. This power of discretion was safely lodged in schools that were state institutions with equipment and financial resource sufficient to meet all current expenses and salaries, regardless of the number of students matriculating—and those with assured attendance large enough to leave out any temptation to admit applicants for financial reasons only. But only a small proportion of the schools have been thus situated. Indeed, most of them must have a given number of students to keep them from bankruptcy, and so at least there was a door of temptation open for the acceptance of credentials that ought to have been better than they often were. In fact at Niagara in 1899 the chief argument used by college representatives against the fixing of the two-year high school minimum requirement was that it would prove the financial ruin of one-half the schools of this country. But what is the fact? Since the first bar was put up the attendance in dental schools has not only diminished but has increased—at least in all the better equipped schools. The experience of the Medical Department of Johns Hopkins is a great object lesson in this regard. Some years ago, because of the increasing size of its classes, and in the hope of restricting them, the entrance requirement was raised first to high school graduation, and then to the possession of an academic degree, all of which only served to increase the number of applicants for matriculation—thus proving a well-known axiom, that the more highly one holds his wares the more eagerly they are sought.

There is probably no doubt that if the higher standard could be successfully inaugurated and established it would work a very marked improvement in the quality of student material entering our schools, a consummation, from the standpoint of us all, most "devoutly to be wished."

The capacity, education, fitness, integrity and even general intelligence of the average examiner, so glibly and frequently brought into question in our current literature, may be far from ideal, and yet, even he is often startled into protest against much of the graduated product that has been sent out from many of our schools in the past few years.

Accepting, from what appears to be the inevitable tendency of events, the high school graduation standard as a condition to be desired, the question at once presents: How can it be inaugurated without working injury to the college interest? The answer is that the colleges, by joining forces with the boards whose duty it is to enforce the dental laws, can at once establish and maintain, without friction or disturbance to the interest of all concerned, an immediate advance of matriculation standards to high school graduation. This as a general proposition will stand.

However doubtful may be the comparative power and strength, legally and morally, of the faculties and examiners when at variance with each other, there is nevertheless no limit to their power and ability to maintain any given standard of educational requirement within reason—as a basis of accepted reputability before the public—made and provided these two representative forces agree to work honestly together to that end. This fact has been lost sight of too long by the colleges. No matter if the appointment of examiners is dominated by political pulls, or if many of their men are incompetent, dull-headed and far from fit representatives of our ideals (as has often been charged), still it must be always remembered that these men represent and are entrusted with the administration of the law, and the law always dignifies its chosen administrators. No matter if the many state laws bear evidence of weakness and inefficiency and are apparently at great variance with each other in their provisions and standards, if scrutinized carefully they will all be found to demand that colleges shall be reputable. This one feature of uniformity in ethics makes it possible for the teachers and examiners, backed by the moral support of the profession at large, to establish and maintain in every state of the Union any educational as well as ethical standards on which they are agreed to be of one mind.

While the Faculties Association's rules give the individual college absolute control over the behavior, standing, advancement and transfer of the entered students —thus making it impossible for one of them who has fallen short of passing muster in one college to be admitted to another school without the full consent of his alma mater—while, I say, all this obtains after a student has matriculated and been given standing, there is at present nothing to absolutely prevent a man whose credentials have been refused by one school, bobbing up serenely before the dean of another school, and having standing given him on the same credentials. This commercial and competitive temptation, which is the chief obstacle in the way of successfully establishing a uniform advanced standard requirement, can easily and only be overcome by such wise and careful legislation on the part of the Faculties Association as has distinguished it in handling many other no less delicate questions. In the many discussions of this subject of preliminary education the argument has been made, and stoutly supported by facts, that a large number of the most eminently successful of our professions are men who had practically no educational opportunities before embarking on a professional career, and, therefore, that to set a fixed and arbitrary standard would in effect often bar out those who might become, with opportunity, shining lights. Of course, all will admit that such men would be much better equipped with proper educational preparation, and indeed for such very good reason every fixed standard that has been agreed upon or that is contemplated for the future, is modified by the words, "or its equivalent," to give the aspiring student his chance—no matter if his educational opportunities have been curtailed by environment.

How shall a fair, honest judgment as to what constitutes the equivalent of any given standard be secured, and who shall pass such judgment? On this question being properly answered hinges the successful establishment of any prerequisite standard. All will admit that however well equipped a man may be as instructor in any branch of dental education, yet, by that very fact, he is sure to be at least rusty and out of practice on public school examinations, and certainly the college teacher will admit that the politically appointed examiner is likely to be fully as unfitted as himself. Did you ever have opportunity to examine a bunch of material filed with a college dean, called matriculation credentials? It is a startling object lesson, and a few samples will exemplify the plausible expedients resorted to (and, it is to be feared, too often successfully) by men wholly unqualified to meet the published standards of the schools they wish to enter. Ambiguous letters from interested teachers and complacent county superintendents, carefully framed to seem to cover the standard demanded, but really as untruthful as the serpent's reply to Mother Eve, "Yea, hath God said."

Mind, the new Rule VIII, jointly adopted at Niagara in 1899, provides thus: "The preliminary examination to be placed in the hands of the State Superintendent of Public Instruction, as adopted by the State Board of Missouri." Manifestly—since it is not to be presumed that the dental profession has the power to prescribe special duties for any state officer—the intention and expectation was that the State Superintendent of Public Instruction for each state having dental schools should be requested to select and appoint some person specially fitted, in his judgment, to pass upon credentials and properly conduct the preliminary examinations of intending dental matriculants in the colleges of that state. Of course the State Superintendent is a "political creation," but his special appointee for this particular work may practically be satisfactorily agreed upon between the college and the state board. Thus would the college dean be relieved from the ever-perplexing responsibility of passing upon all sorts of so-called credentials, such as every dean has presented to him—credentials many of them so plausible as to easily pass muster if only casually scanned, and which the dean feels certain, should he refuse them, would be cheerfully accepted, along with the student and the fee, by another dean somewhere.

Eliminate all this. Make it absolutely impossible that a matriculant can be given standing in any college on credentials, until these credentials shall have been passed upon, 1, by the accredited representative of the State Superintendent, and then, finally, accepted or rejected by the joint conference committee of college and board. Make their decision, in the interstate and intercollegiate sense, final, and add, if you choose, a reasonable probationary clause providing the applicant a way to make up his shortcomings without abandoning the study of dentistry. In other words, make the general rule jointly accepted at Niagara, practically effective and universal by the two National bodies formulating specific rules for its application in every state, territory and district where a dental school exists. This plan has been successfully operated in more than one state and if it, or some other one equally practicable, could be inaugurated and applied to all schools alike, one of the chief temptations to commercialism and competition rather than emulation, would be eliminated and each school would stand or fall accordingly as its intrinsic merits command recognition.

LICENSING.

I. BY EXAMINATION. II. BY DIPLOMA.*

J. A. LIBBEY, D.D.S.,
PITTSBURG, PA.

There should be no other requirement for entering upon professional work than a diploma from a college chartered by the state for the purpose of educating students, whether it be a classical course or upon some special branch, employing well-qualified teachers, who are thoroughly in earnest in their work and loyal to their profession, and are desirous to see only those who are thoroughly competent, enter it; who count the qualities of the student of more value than the profits of the institution.

It is evident that the schools are not all conducted on a basis like this, for the reason that there must be sufficient funds to defray all expenses, including the assistants' salaries, and sufficient dividend to justify the faculty or incorporators for the valuable time taken from their practice; not considering the added tone and dignity of being called "professor"—which is frequently used for profit.

The question arises: "How many students can we get at a certain rate each?" If one hundred are secured it will be difficult to get sufficient clinics for demonstration; how will this be accomplished? The usual way is to urge the students to solicit, not among the poor and needy, but among their own class of people, who are usually able to pay a fair fee, to a young man who is struggling to build up a practice; and as this business or commercial spirit increases the higher motive of professional education is lost sight of. What is more unprofessional than this manner of solicitation?

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

"A chain is no stronger than the weakest link." If license by diploma is accepted then the poorest school sets the standard for all. Hence the necessity for licensing by examination.

The necessity for examination is not a new idea; it can scarcely be called a modern one, for in 1700 a French writer urges the necessity of examinations in France for the practice of dentistry.

The history of reform in the dental profession in England, by Hill, conclusively shows, not only the necessity requiring examinations, but also the advancement from a scientific and professional standpoint, by which the people were the beneficiaries. On page 86 he quotes the remarks of the president of the Odontological Society (the late S. Cartwright): "It can not be doubted that a liberal education is of the greatest advantage to those engaged in practice, and the more education is extended in all ranks of society the more it becomes necessary that the members of our profession qualify themselves as highly as they can. For those who employ their services in these days have a right to look, and do look, to the qualities of the mind as well as mechanical adroitness of the fingers."

The main object of the above society was to unite members of the dental profession into a recognized body and provide a means of professional education and examination.

In nearly every criticism on dental legislation, or State Board of Examiners, the author gives the impression that the laws were passed for the benefit of the profession; if such were the case they should be repealed, as class legislation is in direct opposition to the principles of our government. The laws were made for the people.

Most of the Christian denominations require examinations for license; the medical laws are similar to ours, and the profession of law requires the same. In the writer's state (Pennsylvania) a law student must pass a preliminary, and after graduation must pass an examination before a board appointed by the court, the only persons competent to appoint that board.

The representatives of the people recognize the necessity of passing laws for their protection from the incompetent practitioners.

The best means possible should be adopted to test the qualifications of the aspirant to professional practice, and the most important is a judicious selection of competent examiners. As stated above, the court appoints the examiners for the law—they are the most competent to perform that duty, but would prove themselves unqualified were it required of them to appoint a medical board.

No one is competent to appoint a board for professional examinations except members in good standing in that profession. The difficulty of securing competent men for examiners in our profession arises from the necessity of their being appointed by the governor, thus making them officers of the state, and he being authorized to appoint, may be ill advised in the selection.

As the court is the representative body of the profession of law, and is competent, the only representative body of the dental or medical profession in the state is the state society, it should be a state society in fact as well as in name, which is not the case in some states. It must be chartered by the state, and to be a representative body must be made up of representatives (or delegates) from the local societies throughout the state. Act of 1897, Pennsylvania, gives the power of appointment to the governor and the selection to the state society (which is a representative body). Section 5: "The Pennsylvania State Dental Society may, at its annual meeting in 1897, and annually hereafter at said meeting, select as nominees the names of double the number of examiners required, who shall be members in good standing of the society, and transmit such names to the governor under its seal and signed by its secretary. From this list of nominees the governor shall, during the month of August, Anno Domini 1897, appoint a board of dental examiners. In case of failure of the said Pennsylvania State Dental Society to submit such list, as aforesaid, the governor shall appoint members in good standing of the said society without other restrictions. Each one of the said appointees must be a registered, bona fide practitioner of dentistry in good standing, and shall have practiced dentistry under the laws of this state for a period of not less than ten years. No member of a Dental College Faculty shall be eligible to appointment upon the State Board of Dental Examiners, but this shall not apply to membership in the Dental Council. The governor shall fill vacancies by death or otherwise for the unexpired term of said examiners, from the list of names submitted to him by the Dental Society."

Since the present law went into effect 823 applicants have been examined; these were graduates from 18 different schools. Of this number, 711 passed successfully and received licenses from the dental council; 112 failed to receive the required average. A fraction over 13.5 per cent. considering[1] "The measure had an *ex post facto* character, inasmuch as when it was passed many students had already spent two years in the dental schools, and in recognition of this fact the Board of Examiners has been lenient in the examination of applicants. This has no doubt aided in fostering good will toward the law. The influence of the work of the Board of Examiners has been beneficial, in that it has given a stimulus to the teaching in the schools and has induced stricter scrutiny of the acquirements of candidates for diplomas. Formerly students often sought the schools from which they could be graduated most easily, but now they prefer those that require a higher standard."

If the Board had marked the first two years, as they have since, the percentage of failures would have been doubled, as fully that number barely passed the required average—75 per cent.

Dr. John Sayre Marshall, president of the Board of Examiners for the Army, reported to the journals that out of a class of 14 applicants (the first to be examined) only 2 passed.

Is this not sufficient evidence that there should be a reform in the system of educating students for our profession? When the profession and the people realize the condition that now exists there will be no difficulty in getting laws passed that will be a real protection against quackery and contribute to hastening the time when the stomatologist will take the degree of M.D., leaving the name "dentist" to designate those who do only mechanical work.

---

[1] Extract from report to the Governor.

DISCUSSION ON PAPERS OF DRS. CARR, PARMELE, TURNER, CHITTENDEN AND LIBBEY.

Dr. Eugene S. Talbot, Chicago—One important part of dental education consists in the appointment of state boards, as well as the quality of the men upon these boards. A great responsibility not only rests upon them, but also great power. These men should be selected from the state dental societies. Twice the number of men required should be selected and appointed (at least the number required by law) by the governor of the state. Good men are thus secured, their appointment is legal and it places the responsibility. The proper men can wield a great power, and they do as it is, but if they were qualified men, of high ideals, of education, the specialty would be placed where it belongs. I believe these men can control the colleges and place the entrance and financial examinations exactly where they should be. That the graduates are not up to the standard has already been shown in the examinations made in the army through the National Examining Board for the Army and Navy. I have received a letter from Dr. Marshall in which he says 42 graduates have been examined and only 11 have passed. This shows the graduates of our dental schools are certainly lacking in some particulars. This has already been noted in an editorial in one of the journals, showing great interest in the symposium of last year. Dr. Marshall's report shows something more is lacking, and no doubt the agitation of these subjects will be productive of much good at the next meeting of the National Association in Milwaukee. This editorial hoped the men would not return to their homes without advocating the introduction of a four-year course in every dental college and I believe the time is coming when a four-year course will be demanded, thus giving the student a firm foundation for his life career.

A four-year course will necessitate a better understanding of the subjects the teacher has under discussion. Pathology, of which the student and the profession alike know very little, will and should become one of the principal branches. The bacteriology of the mouth, a great factor in diagnosis, is really a department of dentistry, and yet the first principles are scarcely taught or understood. The etiology of diseases of the mouth is yet in its infancy, and the coming dentist must not only be a "plugger of teeth" but an all round pathologist.

Dr. Vida A. Latham, Rogers Park, Ill.—I think the solving of the whole question comes with the preliminary education—registration. The candidate enters the Northwestern University, the Chicago Dental School, or any other dental college. The candidate applies for entrance just as those Dr. Chittenden has mentioned, and is permitted to register, let us say, on a high school or university diploma. The city of A has a good high school whose certificate indicates a sufficient preliminary English education. But another candidate with a diploma from the schools of the town of C can perhaps hardly do more than write her own name! There are all kinds of universities and high schools, unfortunately. Compare the schools and universities of Duluth, Chicago, and New York with those in certain other places. How can you make them equal in subjects or standard? Yet any of their graduates might register in a dental or medical college on these diplomas, however unequal their qualifications. The trouble is in standardizing the elementary requirements in every case.

There is another thing to be brought out in this connection. Supposing I advertise; supposing I am a quack! The College and state board do not take my diplomas away for misdemeanor! I can move into another state and practice again! These are the things that should not be tolerated in this country, especially as it is doing damage to our colleges. We meet with this matter of diploma everywhere.

Dr. R. R. Andrews, Cambridge, Mass.—There are a few words I wish to say in regard to raising the standard of the examinations of the boards of registration of the different states. In New England they are trying to equalize the examination in each state, so that a student may take the examination in one state, and practice his profession without taking another examination in any of the New England states where he may wish to practice. This reciprocity among the states is what the profession at large will demand. Public opinion in the profession is strongly in favor of such a movement, and if the National body will adopt a standard and live up to it, a man who shall once pass a state board can have the privilege of practicing in any state in the Union without further examinations.

As the law stands to-day, a man may pass a creditable examination in all points. At the end of five or ten years, on account of sickness or something else, he is compelled to go to another state, where he expects to practice his profession. He has his diploma, which he has earned, and his certificate from his state board, stating that he has been examined and found worthy. He has passed five or ten years in honorable practice, and with this record he should be allowed to continue without further examination; but as the law stands to-day, this man, with all his experience, has got to go before the board of that state and pass an examination, the same as the young man just graduating. What we want, and what the profession will soon demand, is that a man having once passed a creditable examination of the state examining board in one state, shall be allowed thereafter to practice in any.

The National Board should consider the matter of giving to the different state boards certain rights, in considering cases where a man has been engaged in honorable practice for twenty or thirty years, and who is obliged through illness to go where he is ordered by his physician to regain health. I have in mind the case of one of the founders of the Harvard Dental School, a man of thirty-years' active and honorable practice, one of the most able operators in the city of Boston, and respected by all who knew him. He was ordered West by his physician. After awhile he was called before the state board of examiners and candidly confessed that he could not pass their examination in chemistry, bacteriology, and other scientific courses presented, but stated that he could give them abundant testimony of his ability to practice his profession. He did not take the examination, but came North, and took a college course which admitted him to practice. The board is established to protect the public; can anyone doubt that with this gentleman's high standing, eminent ability, and years of experience, he was unable to fulfill every demand?

I have in mind the case of another who was graduated from one of our special schools in Boston. He went to Germany, and was in practice with his brother for a number of years. He is a fine operator; he is so good a mechanical operator that he is to-day employed as one of the instructors in that department of one of our schools. He is a very nervous man, who is easily rattled by an examination. Coming back to this country, and wishing to practice, he went before the board, but became so nervous that he could not pass the examination. In this case, there is no question but what the public would be well treated if he had been registered. I am myself an advocate for a good solid examination, but the examinations given by some of our boards, especially by new men who have recently come in, have in some cases been severe, with catch questions. It has been acknowledged by members of the board in our own state that it would be very difficult for them to pass their own examinations. It is a fact that a member of the board of a neighboring state was compelled to move to Massachusetts, tried the examination and was turned down. This question is one of great importance. There must be reciprocity between the states, and the sooner this matter is considered by the National Board, the better.

Dr. Charles Chittenden, Madison, Wis.—I think there is scarcely a board in existence that does not consider the number of years a man has had in practice. In Wisconsin our Board has in its code of rules a rule something like this: "Candidates having had ten years or upwards of practice immediately before applying for this examination shall be required to pass only a 50 per cent. examination." I think that rule applies in a majority of the states.

Dr. George J. Dennis, Chicago.—I am not actively engaged in the work of dentistry at the present time, but the raising of the standard of dentistry is something that always appeals to me. The question came to my mind as I listened to a paper that was recently read, and it also appeared recently in the papers, as to what would be the remedies for raising the standard of dental education. We have talked about dental education for years, and I believe the subject has been often brought up in this Section. Is it to be remedied by law or simply by the good intent of the majority of those who have this matter in charge? By that, I mean the faculties of the different schools or the members of the state examining boards.

The matter of requiring a dentist going from one state to another and failing to pass the examination of the board of that state, it seems to me, is entirely wrong on the part of our examining boards. They seem to fail to recognize that years of labor and years of reputable standing in a community count for very little compared with the examination simply. Examinations of a dentist's ability, as a rule, do not amount to much. I think that is recognized by medical men generally. Oftentimes an examination shows but very little of what a man is capable. This is recognized by examining boards in hospitals. Often in connection with the examination they will take into consideration not merely the quality of the paper that is presented, but the quality of the man, his moral standing, his standing in the community, and his ability in lines outside of mere memory, and the actual tests by presenting human cases of his ability. It seems to me that a dentist who has worked for years in one state ought to be valued for his manipulative ability very much more than to have his standing judged entirely by a written paper.

In regard to the matter advocated in one of the papers, of paying for the work of the examining board by fees from the candidates for examination, I think that method has been so thoroughly tested and proven a failure that it seems to me entirely out of the question to consider it here. The people are the ones who should bear the burden of expense. They are the ones who are being protected by the examining board, and they should bear the expense of the examination.

Dr. J. R. Currens, Two Rivers, Wis.—I am not a dentist, but I am a member of the Examining Board of Wisconsin. We had a meeting of the representatives of the Examining Boards of the United States yesterday in which these matters came up, and what impressed me here to-day is in regard to reciprocity between the different boards. I think if something can be arrived at, and if our laws can be so framed that they give the boards the power to recognize licenses from other states, I can not see but what it is the right thing to do. In the medical profession we have a little more difficulty than you dentists have. We have three or four schools to contend with, and the situation is a great deal more mixed. We have on our board two regulars, two homeopaths, and two eclectics. After July 1 we will have to take on one of our manipulative friends. In regard to this reciprocity business, there are many men who have grown old in the profession, their family surroundings are such, the condition of their health is such that they have to have a climatic change, and it is a great hardship to those men to put them through an examination. The matter of diplomas and examinations came up here this afternoon, and I believe in the medical line we are worse off than you are in the dental line. It is very hard for the State Board of Wisconsin to tell about the standing of a medical college in Alabama or Tennessee. For example, these schools will get out a curriculum that one will read with admiration, but they will take almost anything in the way of entrance requirements. Under our law we can require a diploma and examination both, and we will have such under direct control. It is all right to use a diploma if you know it is from a reputable school, but you can not have a class legislation, and there are very few boards that are allowed to use their discretion unless they have an investigation, which is a rather difficult piece of business. Most boards have to be self-sustaining, and it would be an admirable thing if they could prevail upon the legislators to make the concession, but it is difficult to make them believe that it would be for the benefit of the people instead of the medical men and the dentists. They want us to be self-sustaining, and it places us in a rather bad position sometimes. There was a flaw in our law in the revision of the statutes, so that we could not even send a man out to investigate a case without calling the whole Board together. We had a reserve fund of $1200, and the result was that we had to turn it into the treasury. We tried to get it back, but could not do it. We had no money to investigate anything; the state has the money, and it will stay there.

To my mind, the solution of the whole matter would be this: In the first place, raise the standard high. See that the primary education is brought up to a high standard. In regard to the high school standard which has been referred to, we have a clause in our medical law which provides that the high school standard must be up to the high school standard of our state. In that way any difficulty can be obviated very easily. One medical college fought very hard against the high school standard, and we had to cut it down to the junior year, but we expect to raise it two years from now. We have got to go slow in these things, and in this reciprocity business try to get the state laws on the same plane, and if we all join hands the matter can be accomplished. The laws are queer things to handle. There is that word "reputable" that is in the law. If a man is from a reputable college, the board has some discretionary powers, but if you get too particular about it, the board may decide you are a little too strict. It is a hard thing to learn the ways of the law. We had a case before our Board. Our law of 1897 was a very fair law. A disreputable individual took several courses in some Omaha medical college, and they refused him graduation. They pretended he did not come up to the standard. The fact was he passed a good examination, but it was on account of his moral character they refused to graduate him. The result was he went to St. Louis and graduated from the Barnes Medical College. He then went to North Dakota, and the Secretary of the State Board of North Dakota wrote to our secretary that the man was disreputable and doing all kinds of dishonorable things. He ran a lightning-rod business. He would go to a farmer with twelve children and tell him if he would give him a note for $100, he would take care of his children for twelve years. He took notes and sold them to some banks. He did the same thing in Iowa and Nebraska. Then he came to our state and wanted a license, and we refused him. We supposed our law was all right, but there was a revision of the laws in 1898. Our Board was a little afraid about those session laws of 1898, but we supposed they were all right, but they changed the wording somewhat and the punctuation, thinking it would come out all right, but if you take these things before a jury they do not always come out as expected. The case came before a jury and the fact of the matter was he beat us and we were obliged to license him. Now, he threatens us with personal damage suits.

Dr. R. H. Nones, Philadelphia—I am interested in the symposium and the various talks I have heard, and the whole question is a matter of cause and effect without arriving at the proper remedy. There are some apparent remedies, but to select one that would answer every case is a difficult thing to do. If we do seemingly find a remedy, one problem succeeds another until we find it is impracticable. How would you take care of the older practitioner if he wanted to move from one state to another? That would immediately be fought in some states that did not want a man to come over from another state, and that brings up the question of the survival of the fittest. It is a very well-known fact, yet a very sad one, that if a man has been in practice for some years, and he may be a young man, too, he neglects many of the theoretical branches which the examining board compels him to take. Now, if that man has not taken such an examination that is demanded of the younger men, I do not see how you could get a state board to pass him. It would be somewhat retro-active, to my mind, because he has had the opportunity to have had those qualifications which should fit him to go on in advance of this younger man. It acts in this way, you may say. Many a young man who, as has been suggested, might make a very competent dentist if he had those qualifications in later years. Why should not that young man have this same privilege to enter and bring up the necessary qualifications as the older man has, where you give him credit for forgetting his earlier qualifications? I say this problem and many similar problems have come to me. We have tried to get too many things instead of getting one good thing at a time. We started with too many things we wanted, and received nothing. I believe had the Association of Dental Faculties incorporated into their act or law, or whatever it was that was passed, a curriculum that should have been passed by the student: his preliminary education would have been much better than by grading the standard to one, two or three years, whatever it may be, of high school. With all the careful thought of these gentlemen they little, I suppose, thought that immediately it was entered upon the question would come up: What is one year of the high school in one state or another? Immediately that trouble arose, and it has been one of the very hardest things to contend with in colleges.

I can verify Dr. Chittenden's remarks in regard to qualifications; I have seen them in all forms. When students presented credentials to me, I have invariably taken their credentials from them and told them I would send them to the Superintendent of Public Instruction to have them passed upon. I think by immediately taking his credentials from a man you can settle the matter for all time. If that credential comes back, I can follow him up in any other school and tell them they have no right to take that man. That is a thing for the deans to look into. The other gentleman who spoke made the point of a faculty being liable to be mandamused. That is a very strong point, indeed. You think you are treading on safe ground when your state board says to a graduate that he is not a graduate from a reputable institution. The question comes up: What is a reputable institution? In order to emphasize that point I will cite the case of the school I am connected with—the Dental College of Philadelphia. We had some difficulty to get our dental college into the faculty. They refused us admission, and we went to teaching dentistry under the charter of the medical college. We sent our students before the State Board, and they refused to examine them. We threatened them with mandamus proceedings, and after consultation with the attorney-general, they were compelled to examine our students; they passed the Board, and shortly after that we were admitted to the Association of Faculties. Other states refused to do the same thing, but they soon fell into line. We were in perfect harmony with the faculty, but the question arises: What is a reputable school? This is a very serious question, particularly the point of getting men whom you would like to see on the state board. Those men, as a rule, are very busy men; men who can not afford to give their time to such a work as this. It is not a pleasure. I have seen a great deal of it. I am acquainted with the State Board of Pennsylvania, and I know the amount of work they have to do. I say there is absolutely no pleasure attached to it. In regard to the matter as to how the men on the state board should be recompensed, that is a difficult problem. The class of men that should be on the board are difficult to obtain, because their time is of a great deal more value to themselves than the recompense they get from the state. I see no other plan except that of the fee being paid by the applicant. It is a matter of the utmost folly to ask the public to pay for such services by taxation. The question is whether they want protection. The general public does not want protection, as a rule. I went through one of the large department stores in Chicago, and it was a matter of surprise to me that in this large department store they are doing dentistry work at "Fair" prices. They claim to do crown and bridge work and such things, and that in the second city in the Union. If the public does not want protection in the large cities, what could you expect in the smaller towns, where you would expect to tax the people for this protection? Would they want it? I say most assuredly not.

There is another point that struck me while listening to these papers, and that is in regard to the matter of Dr. Marshall not passing some twelve out of fourteen. That casts somewhat of a reflection at first thought on the various schools throughout the United States. To my mind, it does not, because I look at it in this light, that the greater majority of those students that are passed upon by the examining boards have made up from one to two years, and you can see at once that it makes it difficult for those men to pass. Again, I say without any hesitation, I believe the majority of the state boards of the United States could not pass their own examination. I say that without casting any reflection, but I do not think these gentlemen have kept up with the various theoretical subjects. It is out of the question to expect them to do such a thing, and I think it would be a point of much interest had Dr. Marshall told us whether it was the theoretical or practical branch in which they were lacking. I have always tried to find out the weak points of my students when they appeared before the state board, and tried to strengthen them on those points in college. I think that is a point the various state boards should give out. It would benefit the schools materially, and in that way the profession at large would be benefited.

DR. A. H. PECK, Chicago— Dr. Talbot has stated that state examining boards have power to regulate some phases of the individual college work, such as the preliminary requirements, etc. If Dr. Talbot's judgment is correct, and in a measure it is, I do hope the day is not far distant when the state dental examining boards may be placed in position where, by special legislation or advancement of public sentiment, or whatever the means, they may be able to successfully use the power that is placed in their hands that the entrance of students to our various colleges may be regulated and placed in the condition it should be, because we all know that the entrance of students to our colleges has not been what it should be. In other words, not to cast any reflections upon any institution, all colleges are pretty much alike in this respect. They pay very little attention, as a rule, to credentials presented by students. Many of them are private institutions, and are in the field for private gain, and whether or not the student who applies for admission possesses the necessary qualifications to carry him through lies with the powers that be. This is a demoralizing condition of things in this phase of dental education, and may the day be hastened when this condition may be eliminated and our institutions placed on their proper plane.

DR. CHARLES CHITTENDEN (closing the discussion).—There is no question about the power of examining boards, provided they have the dental colleges and the dental profession at their backs. Examining boards can do anything it is desired should be done for the dental profession in the matter of standards. As I tried to exemplify in my paper, there is no question but that the boards and the colleges together can do all that there is to be done in this matter. The difficulty has been in the past with the colleges and the faculties associations. For sixteen or seventeen years we have waited for the National Association of Faculties, who said that they would fix the standard; that they could be trusted, and that as soon as they had all schools in they would see that the standard was raised to where it should be, and that all these evils were corrected; but I think now, if the members of the Association were asked, they would admit that they have in the Association many schools that ought not to be recognized. Last year there was a school examined by a special committee of the Faculties Association, and a report brought in, which I had the honor of being permitted to see, prepared to be presented to the Faculties Association, but it was so scathing in many of its criticisms of the school that had been examined, that the report was withheld. I hope to see that report brought forward some day and the school properly dealt with. The Faculties Association feels it has a lot of weak schools represented, but it does not want to cause a disturbance, and the result is they have nothing by which to hold up the standard. They do not seem to remember that they should come to the examiners and join hands together and settle upon a standard; they do not stop to think that there might be a more successful method.

A gentleman said he would like to know in what branches the students were most likely to fall down. Our experience has been that students fall down first in simple anatomy. Next, they will fail on a dozen questions that almost any child in a common ward school should answer. That has been our general experience.

I desire to append the following letters, which speak for themselves:

Wisconsin, July 29, 1899.

"Gentlemen of the School of Dental Surgery.

"The bearer, ———, of this city, is a young man of good moral character and a very good student. In the year 1896 he was qualified to hold a second grade certificate to teach school in ———, which was equivalent to a three-year course in the high school of this city.

"Supt. of ——— School from 1894 to 1896."

"Dr. ———, Chicago, Ill., Dear Sir:

"Mr. ———, the bearer, impresses me as a young man in every sense qualified to take a dental course.

"He states that he completed the graded-school course and a portion of the first year of the high school course in the city of ———. Since then he has had several years of practical experience in a telegraph office in this city.

"Respectfully,

"Asst. State Superintendent.."

POST-OPERATIVE HEMORRHAGE.*

A. H. CORDIER, M.D.

President of the Mississippi Valley Medical Association: Professor of Abdominal Surgery, University Medical College.

KANSAS CITY, MO.

I know of no condition in my work that is more horrifying than to realize that a patient upon whom I have just performed an abdominal operation is bleeding dangerously. I know of no condition under which the surgeon will more quickly realize the importance of his work and appreciate more fully the great responsibility existing in every abdominal operation.

An avoidable accident to a patient that may result in the death of that patient is a very serious matter and should not be passed over as a trifling affair by the surgeon. Trying to give contentment to the sorrowing family and friends by assuring them that the all-wise Providence willed it thus may satisfy the unsuspecting and confiding family circle; but does it relieve the mind of the surgeon or save the patient?

The use of unstable ligature material on large pedicles and in localities where the same is quickly absorbed has cost quite a number of patients their lives from post-operative bleeding. It has been my misfortune to lose one patient from a post-operative hemorrhage, the cause being the use of a catgut ligature. After a large series of cases in which I used silk (I use it altogether now) without an accident of this character, I was persuaded to use catgut in a simple and easy case. This case was in a private residence in a distant city. Three hours after the operation my patient died from hemorrhage, the result of a slipped catgut ligature. I know that the ligature was responsible for this death. It should have been avoided. Dispensations of Providence are garments that may be used to hide the naked truths from an ever-credulous public, but before the eyes of the conscientious surgeon he sees the slanderous injustice of hiding his blunders under such sacred raiment.

That many fatal post-operative hemorrhages are unavoidable no one will deny, and it has been the experience of almost every surgeon to have had such. The recognition of the possibility of a patient's bleeding to death following an operation should only make the surgeon more careful to avoid it and to resort to the best method of speedily checking it when it has taken place.

There is no condition in which quick surgery is more essential; I mean by quick surgery, not alone getting at the work quickly, but rapid work after the secondary operation has begun. A patient who a few hours previously has gone through a severe operation, probably of long duration, or of a character to produce shock, is not a very good subject to be given an anesthetic and undergo a reopening of the peritoneum. If the surgeon does not recognize this, the majority of his patients who are reoperated upon will die. No chronic or deliberate surgery can be tolerated by such a patient.

The use of the Trendelenburg position, while it enables the surgeon to see the bleeding points and to tie them most efficiently, may by gravity, in a patient with a weakened heart, keep a vessel from bleeding during the operation that may bleed profusely on the patient's assuming the horizontal position when placed in bed. This is especially true of capillary oozing from adhesions.

The drainage, as has been urged by Price and others, is not only valuable as a sentinel, but has a direct hemostatic power. All recognize the necessity of a clot, firm in character, to control oozing or even bleeding from larger vessels. Blood in the air-tight peritoneum, in the presence of a peritoneal temperature and abundance of lymph, will not coagulate quickly or at all firmly, as all will agree who have opened the peritoneum in cases of ruptured tubal-gestation or other conditions where there has been a free intraperitoneal bleeding.

A drainage tube in suspected cases for a few hours will do no harm and will surely give the indications of a hemorrhage. If the bleeding is from small vessels, the keeping of the peritoneum dry will be a potent factor in controlling the bleeding. Of course, the tube should not be used unless some reason is present for its use.

While the tube is of much use in suspected cases, its utility is lost in the case where a hemorrhage occurs in a patient in which such an accident is not expected. Thus, my three post-operative hemorrhages have been in easy cases where such was least expected. My other secondary operations for bleeding have been in patients of other surgeons. I was called in their absence, saving the patients in each instance.

The symptoms of a concealed hemorrhage are very much like those attending shock, and, if the symptoms alone were relied upon to make a diagnosis, many errors would result. The pulse is increased in frequency in both, and diminished in force equally in the two conditions. There is a sighing respiration in each, the features are pinched and the surface is blanched in the two, the skin is clammy in both, the patient is comfortable and indifferent in each, the pupils are dilated and respond slowly in either condition.

How is the diagnosis best made? Take, for instance, a fairly strong patient, remove an ovarian tumor from that patient, occupying from fifteen to twenty minutes in the operation. There are no adhesions, there is a small pedicle, a silk ligature is used, and the patient is put to bed in good condition at 9 a. m., with the pulse 80, the temperature 98 F., and with no shock. Now visit this patient at 3 p. m. the same day, and find her with pupils dilated, features pinched, free from pain, the skin white as marble, the lips shrunken and pale, the pulse 160 and very compressible, with a cold, clammy perspiration, all symptoms of shock or hemorrhage. Analyze the history of this case, and experience will say that a patient leaving the table in the condition of this patient, having had no evidence of shock or anything done to produce shock, has an internal bleeding from a broken or slipped ligature; the doubt, if any existed, should be quickly dispelled by cutting a suture and introducing a tube or an artery forcep.

Take another case: Extensive bowel adhesions have been separated in enucleating a growth, the operation is a very long one, the patient is more or less shocked at the completion of the operation, this condition continues until it assumes an alarming state, and the question arises: Is this a continuance of the shock, or is it in part, or altogether, due to a bleeding? If a tube had been introduced, no doubt need exist, but in the absence of the tube there is nothing absolutely reliable to guide us but the cutting of a suture and opening a small portion of the wound. This can be done with absolute safety.

---

* Read in the Section on Obstetrics and Diseases of Women, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

On the other hand, if this patient had left the table in good condition, and a few hours later presented the shock-hemorrhage picture, it would be quite safe to diagnosticate hemorrhage and act accordingly. As a rule, the first evidences of shock begin during the operation, and many cases of secondary shock in reality are cases of post-operative hemorrhage. Each case is an individual; the experience of the operator and his knowledge of what was done, and who did it, will lend much aid in determining the cause of the symptoms manifested, as well as the probable location of the same, if from a bleeding surface or vessel.

If convinced that the patient is bleeding and that the loss of blood will prove fatal, the surgeon's only duty is plain, and he should not shirk it, while giving strychnin, using hot applications, etc. The patient is not safe until the bleeding is controlled. I do not mean a slight oozing such as we often see in the tube in adhesion cases, but by hemorrhage a loss of blood that *quickly* shows its dangers by the rapid failure of the patient's vital forces.

It has been my misfortune to lose one patient operated on from a hemorrhage coming on a few hours after ligating a small pedicle with catgut. The abdomen was reopened, but the patient was dead or had ceased breathing when I had begun. The abdomen was full of blood. I have reopened the abdomen in two of my cases besides this fatal one; in both large quantities of blood were lost, but in both recovery followed. In two cases in the practice of other surgeons I reopened the abdomen, saving both patients.

The proper use of the deci-normal saline solution in restoring patients in cases of shock and loss of blood is one of the most valuable additions to our work within the last few years. Its application is so simple and easy and its powers for good are so large that I am surprised that it is not more extensively employed by the profession. The introduction of air into the vein at time of infusion should be avoided, yet the danger from this source is not so great as is generally supposed. In one of my cases a faulty apparatus permitted a large amount of air to enter the vein. This was done by one of the nurses handling the bulb of the apparatus in such a manner that it let in air. Not a symptom was produced by this accident. I have in all my cases, save this one, used an ordinary fountain syringe and the cannula of an aspirating outfit or, as in one case, the glass nozzle of an ordinary medicine dropper. Everything about the apparatus must be carefully sterilized. The salt should be baked and the water, when possible, filtered and always boiled. The height of the fountain will govern the pressure. Usually a 3-foot pressure is all that is necessary. The fluid must be kept at a uniform temperature of 112 F. in the bag. A lower temperature will frequently cause the patient to "chill." I think it best to introduce the fluid in two sittings where a large amount is necessary. About 90 grains of common salt to a quart of water is approximately a "deci-normal saline solution."

CONCLUSIONS.

1. In diagnosticating post-operative hemorrhage the operative history will aid much.
2. The symptoms of shock and those of hemorrhage are very similar.
3. In suspected cases the cutting of a single stitch in the incision will tell.
4. The surgery must be quick and decisive in these cases.
5. In cases in which bleeding is expected the tube should be used.
6. Large quantities of deci-normal saline solution will save many patients. This should be used both per rectum and by injection into the veins.
7. Strychnin, belladonna, etc., will not control bleeding from a uterine or ovarian artery any better than from any other artery.
8. The surgeon should do what his surgical conscience tells him is right. Late researches in hematology make it appear that an internal concealed hemorrhage may be demonstrated by a careful blood-count. This, it is stated, will show a decrease in the red cells and an increase in the white.

Very similar symptoms accompany shock from various causes, such as internal hernia, etc., none of which produce a change in the red cells. If an operation was performed for the relief of an inflammatory process, this test would lose its value in part, as there would exist at the time of operating a leucocytosis. Saline infusions apparently increase the white cells at first.

DISCUSSION.

DR. L. S. MCMURTRY, Louisville.—In my brief remarks I shall allude to the prevention, diagnosis, and treatment of this condition. We all recognize that post-operative hemorrhage is due to either a broken or a slipped ligature. In my judgment, it is rarely due to the former, and almost invariably due to the latter. I must disagree with the essayist that the ligature material used has much to do with the causation of hemorrhage. I myself, like the essayist, prefer silk, but I recognize the fact that there are gentlemen present who use catgut uniformly, and they can show just as few instances of post-operative hemorrhage as can those who use silk exclusively. After all, it is not so much the material used as the method of application. The man who is in the habit of using one kind of ligature gets accustomed to it and applies that ligature with more celerity and security than if he changes his method frequently. A man who is in the habit of applying catgut to a pedicle or vessels will succeed just as well as he would with silk. Care must be observed in the application of a ligature. For example, in the operation for the removal of uterine fibromata the broad ligaments are usually in a state of great tension, and if the ligatures are then applied and divided, you are inviting the accident of slipped ligatures because just as soon as you relieve the tension, the tissue shrinks and the ligament is apt to slip out of the grasp of the ligature. This accident can be prevented by securing the broad ligament with clamps, and then when there is no tension apply the ligature, place it carefully home, and make sure that it is of good and tested material. As to the prevention of this accident, then, it depends for the most part on the care and surgical precision with which the ligature is applied.

The diagnosis is to me a matter of great difficulty, and the importance of it can not possibly be exaggerated. Secondary operations in the abdomen are fraught with the greatest peril. A patient who has had an operation performed on one day and is obliged to submit to another on the next day can not be expected to bear up under the severe strain and shock. These patients will usually collapse and die, even though the post-operative hemorrhage for which the operation is performed, may have been very slight. You can take a woman with a ruptured tubal pregnancy and with the abdomen full of blood, open the abdomen, occupying nearly an hour, perhaps, in doing so, and she will not have the same amount of shock. The question of interference for the prevention of post-operative hemorrhage is the most difficult, in my judgment, that the surgeon has to decide. Lives have been lost by deciding to do it, and lives have been lost by deciding not to do it. The question must be decided with great care and deliberation. In neurotic women, the circulation and respiration are markedly increased in rapidity after abdominal operations, and it will test the judgment of the most experienced surgeon. Patients with rapid pulse, sighing respiration, neurotic temperament, exhibiting the symptoms the result of neurotic influences, will so simulate post-operative hemorrhage that it will require the greatest care and judgment when making a diagnosis. Therefore, it must not be decided hastily.

The intravenous injection of normal salt solution should never be done when it is possible that the hemorrhage is still going on, because it will be increased on account of the open vessel. The treatment should consist in operative interference decided carefully and judiciously, and which should be executed promptly and rapidly. I do not believe with the essayist that the amount of blood lost should be an indication for or against the interference in post-operative hemorrhage. Oftentimes you will find profound collapse and death occurring from the loss of almost an insignificant quantity of blood. On opening the abdomen of a woman who has had one operation which was followed by symptoms of hemorrhage, you will sometimes be surprised to see how little blood has been lost. There may be just oozing from the venous surfaces, and which will lead to disatrous result. I have opened abdomens and found pedicles intact, but on the side of the pelvis where the adhesions were severed, there was a little trickling of venous blood, and the patient almost gone.

Prompt hemostasis must be performed, and you can not expect to tie vessels when there is oozing, but arrest hemorrhage by quickly packing the entire cavity with gauze. There is no procedure in this department of surgery that requires the exercise of such good judgment and judicious action as is required in the treatment of post-operative hemorrhage.

Dr. Seth C. Gordon, Portland, Maine—Since 1884 I have used no suture or ligature except catgut, with the single exception of silkworm gut, for the closure of abdominal wounds. I believe the time is coming when we are all going to use absorbable sutures and ligatures. In my own experience, I still have to see the first intraperitoneal hemorrhage. I never tie off the pedicle without using a needle, threading one end of a long ligature and carrying it through the pedicle below the ligature, then double-wrapping and firmly tying it. In all cases of hysterectomy, where I am to remove everything, I ligature with the needle as described. I put on the clamp and commence my first ligature by tying the ovarian artery tightly, then carry my needle below that, make another knot, which prevents hemorrhage. The rest is the same, over and over, down to where I cut off the uterus. It is all done with one suture. I certainly would not use a drainage tube in order that I might be protected against pelvic hemorrhage.

Dr. Howard A. Kelly, Baltimore—I am very glad to hear this timely subject brought up for discussion. My former associate in the Johns Hopkins Hospital, Dr. Clark, who is here, will probably recall a case we had some six years ago, where eight days after the operation a woman died from hemorrhage from the right uterine artery, which autopsy showed to be due to the absorption of catgut. Since that time I have preferred to use absorbable ligatures upon what I call cardinal vessels, the two ovarian and uterine arteries. Furthermore, I see no reason why we should desire any other material than fine silk aseptically used; with that, and with gloves worn at the operation, the ligatures will never trouble you afterwards. It is of extreme importance in this work to avoid the antiquated method of tying the pedicle by a ligature which transfixes it and is then tied both ways. The proper ligation of the ovarian pedicle is one ligature at the brim of the pelvis, and the other at the uterine cornu. It is as a rule best to put two ligatures upon all the principal vessels. The most important step of all in the avoidance of hemorrhage is the thorough systematic review of the entire field of operation before closing the abdomen, looking over all ties, and pronouncing a definite judgment on each step of the operation.

The best assurance that there is not going to be any hemorrhage lies in the satisfactory conduction of the operation, so that when the patient lies later in a collapsed condition, and the assistant or nurse is rather doubtful as to whether there is any hemorrhage, the operator can say with positive assurance that he knows there is none. The operator and his assistants ought to inspect the patient carefully as she leaves the table; to examine the pulse and the mucosæ, to get an exact idea of her condition, and in order to make comparisons later to determine whether much blood has been lost. If the operator is unable to say whether or not there is hemorrhage, open up the patient at once, and see. If the patient is a collapsed neurotic, it will not hurt her; but if she has hemorrhage, prompt action will save life.

I give salt solution under the breasts, and as the patient goes onto the table. Do not stop to pick out the exact seat of the hemorrhage. You know which vessels it may come from; therefore, go down into the pelvis with fingers and clamps, catch them all, both uterine and ovarian, then clean out the blood and search for the particular source of the hemorrhage.

Dr. Henry O. Marcy, Boston—I believe that hemorrhage is usually the fault of defective technique. First, the vessels should be sought for and ligated. Then, it is important to suture the tissues over the vessels of these larger wounds so as to have additional control over the ligatures. I earnestly advise the folding of the peritoneum over the stump, as it also prevents hemorrhage, and the possible subsequent adhesions, which otherwise may result. I emphasize this from the standpoint of experience. I believe my best contribution to surgery is the buried animal suture, which I first employed in 1870, and have used it almost daily since. Until 1882 I used only catgut, and with reasonably satisfactory results, but in the long experimental studies that I made on animals, I found that catgut was absorbed much too rapidly, and that the knot is not satisfactory. Then I introduced the tendon suture, as a substitute, which I consider in every way superior.

I take issue with Dr. Kelly in regard to the rubber gloves and the silk, as they do not always prevent the condition he speaks of. I have often found that silk ligatures give rise to irritation and serious subsequent trouble. I am convinced that we should use only absorbable ligatures and sutures, and in such a way that we may be doubly sure that we have control of hemorrhage before the patient leaves the table. We should intrafold all abraded surfaces in pelvic or abdominal wounds, so that we may not have the condition Dr. McMurtry referred to, namely, oozing surfaces. Faulty technique is undoubtedly the most frequent cause for the occurrence of complications of any kind. I have used buried animal sutures in fully three thousand cases of abdominal operations, and I assure you that I have yet to see any reason why I should not be more than ever an enthusiastic advocate of their general adoption in all aseptic surgery.

Dr. Frederick Holme Wiggin, New York City—I have found chromicized catgut No. 1, or No. 2, to be a much more satisfactory material for ligature or suture than silk. In former years much trouble frequently resulted from the use of silk for this purpose, not only in my own work, but in that of others. Frequently, in the course of my service at the City Hospital in New York, in past years, I have had occasion to remove silk ligatures and sutures employed by other surgeons at previous operations, but at the present time, since the use of catgut for suture and ligature material has become to be more generally used, these operations are becoming infrequent. If chromicized catgut is used, taken direct from the alcohol in which it is preserved, there should be no trouble in its being absorbed too soon or of its infecting the tissues. It has been my practice, whenever possible, to pass ligatures around the vessels to be tied by the aid of a needle, and when this is done and the catgut properly tied, there is no possibility, in my opinion, of their slipping. One of the causes why ligatures of catgut or other material slip is that there is too much tension applied to the parts when the ligature is being tied. Another reason why operators often fear to use catgut ligatures is because they find when they tie them the knot frequently comes undone. This is because they do not understand how to make the knot. They tie the catgut ligature as they would one of silk, namely, with a double loop first, followed by a single one. When the knot is tied in this way, it will very often become undone. Some years ago, Dr. C. C. Frederick, of Buffalo, called my attention to the fact that catgut, tied first with a single knot and then with a double surgical knot, the ends of the catgut being left reasonably long, would never slip. Since that time I have used catgut for ligatures entirely in my work, and have had no reason to regret its use.

The surgeon should aim, in my opinion, to tie the vessels as directly as possible, including as little other tissue as is absolutely necessary.

I would like to call attention to the following important point: Where abdominal operations are performed on patients in the Trendelenburg posture often when the operation is completed there is apparently no hemorrhage, but in many cases when the patient is lowered into the horizontal position, you will find on looking about the pelvis, bleeding points. I have often found that if I had not been careful in looking over the field of operation after the patient had been lowered into a horizontal position, I would probably have lost the patient from hemorrhage.

I believe that when catgut is probably used, there is no danger of hemorrhage occurring from vessels tied off with it.

Dr. C. C. Frederick, Buffalo—I have used catgut exclusively for ten years, and in nearly a thousand cases, and I had only one case of slip ligature. That was in a vaginal hysterectomy where the pedicle had been pulled down a great deal during the operation. I believe that was the cause for the ligature slipping.

As to the point made by Dr. Kelly, that the catgut absorbs too rapidly, and that the plug occluding the vessel may be extruded by arterial pressure, and then have hemorrhage, I think that possibly may be true. Formerly, the catgut was sterilized by the Cumol method or alcohol under pressure, being raised to a temperature of 212 and above, rendering it rapidly absorbable. With the modern method of sterilizing, however, I am positive that the catgut is rendered more durable in the tissues. I refer to the formalin process. I know positively that the catgut so prepared is not absorbed until two or three weeks afterwards, hence Dr. Kelly's objection to it cannot be sustained.

Insure against slipping of the ligature by drawing the first knot up tight, and then make the double knot. Do not cut the ends of your ligature too short. There is absolutely no objection to leaving one-half or even three-quarters of an inch of catgut. It aids in preventing the slipping. That is the method I have followed in all my cases.

Dr. M. L. Harris, Chicago—I wish to enter my protest against the ligation *en masse* of large pedicles. There is scarcely a place nor time in abdominal or pelvic surgery where this is necessary. In most cases where secondary hemorrhage has occurred it will be found that the ligature has been applied to the pedicle *en masse*. We should invariably follow the sound surgical rule of applying the ligature directly to the artery or the bleeding vessel. If we ligate *en masse*, the tissue about the vessel may shrink, releasing the vessel, and hemorrhage is sure to follow. In all cases where there is a large mass which bleeds, this should always be closed by a suture, passed with a needle, and in a continuous manner. This will prevent not only the hemorrhage from the vessels, but also the oozing. I think there is no time or place in abdominal or pelvic surgery in which the mass ligature should be applied.

Dr. G. B. Massey, Philadelphia—It seems to me that one side of this question has been somewhat neglected, namely, the future effect on the patient of the material used as a suture. The question of secondary hemorrhage brings up that of the relative value of absorbable and non-absorbable suture materials, but the discussion has been neglected on that side of the question which comes closest home to those of us who are not surgeons, and who see these cases after they leave the surgeon, sometimes years afterwards. I allude to cases of so-called post-operative neuroses. I have seen many of them, and have one under treatment now, in which the suffering seems to have been caused by some irritable focus situated in the uterus, which is partly removed. There is a tender mass in the situation of the remainder of this organ about the size of half a walnut. This patient was operated on six years ago, and since then she has been obliged to spend her mornings recumbent. I do not know what kind of sutures were used, and I merely wish to emphasize that there must be some reason why the surgeons are changing their suture material. I do not believe that non-absorbable material should be left in the body if it can be avoided. Something ought to be used that will disappear by absorption.

Dr. Cordier (closing the discussion)—The principal object of my paper was to call attention to the fact that we must not trust too much to nature in controlling hemorrhage. It is surprising how much we do risk in these cases when we would not think of risking anything in the axilla or popliteal space. Frequently, in abdominal operations, we let oozing go on and trust to nature.

Another point is the question of diagnosis. You find that they will frequently say that the patient was placed back on the table and the incision reopened in order to determine the existence of hemorrhage. This is useless. If the question is whether you have an intraperitoneal hemorrhage, it is necessary to have everything thoroughly sterilized and keep the patient in bed, so as not to disturb her. Clip a stitch and introduce a long sterilized forceps into the wound and detect the hemorrhage. That is the easiest and safest way in which to determine it.

I would never think of using a saline solution while the operation is going on, as the vessels are all widely open and it would simply increase the hemorrhage. However, the hot solution thrown into the rectum is very beneficial in these cases. It matters not what ligature material you use. We always find a diversity of opinion on that subject. A number of gentlemen have talked about absorbable material, and each one has a different opinion as to what should be used, and how. We are dealing with an uncertainty, as regards hemorrhage, when we tie a pedicle with catgut ligature. I have seen them absorb in three days, which is certainly too soon. In regard to the mass ligatures, I do not know how we can get around it; we sometimes have a very broad pedicle and time is an important factor. If you want to undertake and divide these tissues, picking out the individual vessels, you will take up a great deal of time. I do not see any reason why we should not use the mass ligature. One of the safe courses in the use of silk is to tie in a mass ligature, so that the structures will overlap the ligature, and the two surfaces above and below come in contact, and the pedicle remain alive. It will get up an anastomotic circulation, and the ligature will remain clean. When you get silk infected you can not tell what will become of it. The same applies to chromicized catgut, tendon, etc. I have seen it working out of a hernia case twelve and fifteen months after the operation, and I am sure that it is less certain than silk. Where you use silk, you do not have to dance around and see how to use it. Put on a good stout piece of sterilized silk, and in the majority of cases you will have no hemorrhage.

Hemostasis of the Liver.—Baldassari inserted wedge-shaped fragments of decalcified bone between the lips of the wound in the liver, in his experimental research on dogs. The wound was then sutured, including the intermediate bone in the stitches. When the animals were killed later there were no evidences of the slightest oozing of blood or hemorrhage from the wound, and the bone was absorbed, cicatricial tissue taking its place. The bones were rinsed in an acid, then in 50 per cent. alcohol containing a little sublimate, and finally soaked in a hot saline solution to remove the sublimate and soften them.

THE ADVANTAGES AND DISADVANTAGES OF DRAINAGE AFTER ABDOMINAL OPERATIONS.*

HUNTER ROBB, M.D.
Professor of Gynecology, Western Reserve University; Gynecologist-in-Chief to Lakeside Hospital.
CLEVELAND, OHIO.

If the short paper which I present to you to-day is productive of any good results, personally, I look for them not so much from the paper itself as from the discussion which I hope it will inaugurate—"many men, many minds." I do not expect that all my hearers will agree with the opinions which I have formed after some years' experience, and I trust that to-day the views of not a few will be freely expressed in order that the subject may be thoroughly thrashed out. In short it would seem advisable for us to hold what may be termed an "experience meeting" and my remarks may simply be looked upon as prefatory to what I hope may be a full and fruitful discussion. I shall speak briefly of work done by others and by myself sometime ago, and shall supplement this by my own experience in two series of cases, in the first of which there were 114 and in the second 108 consecutive, unselected, abdominal sections without a death.

During the past few years our ideas regarding the necessity for and the efficacy of drainage in abdominal surgery have undergone the most radical changes. Not so very long ago we did not venture to close the wound of any abdominal section absolutely but left in a large tube which reached well down among the tissues. It was then thought that infected cases—such, for instance, as pelvic abscess—could never recover without drainage, and that even in the cleanest cases it was always well to insert the tube for at least a few hours until the so-called serous oozing had ceased, in order not to tax too severely the absorptive power of the peritoneum.

In a paper published in 1890 I summarized the indications for drainage as follows: 1, to provide a means of escape for the serous oozing which follows the separation of broad adherent surfaces; 2, to guard against septic peritonitis from retained pus from the tube, ovary, or other viscus; 3, to remove fluid in cases of persistent capillary hemorrhage; 4, to provide against hemorrhage in cases of hysterectomy when the pedicle is dropped; 5, to drain the peritoneal cavity and starve out the disease in cases of chronic or tubercular peritonitis.

But after our attention had been called to the importance of taking more pains with the minute operative details; after we had recognized the necessity of checking all hemorrhage, even from the smaller bleeding points, of avoiding any infection of the field from the contents of abscesses or of the intestines, and of making a careful peritoneal toilette; above all, since we have understood the effects of any rough handling of the tissues, we have come to look upon the necessity for drainage as being the exception rather than the rule.

Again, in 1891, after having made a series of bacteriologic examinations of the secretions found in the drainage tube and upon the gauze placed in the tube for drainage, we became convinced that the drainage-tube was frequently the avenue through which septic infection took place. In many instances the fluids in and around the tube would contain few or no bacteria at the first examination, whereas upon a second or third examination many micro-organisms were found in the secretions thus examined. As a consequence of these and similar results the objections to the insertion of drainage-tubes were formulated by Professor Welch of the Johns Hopkins Hospital as follows:

"1. They tend to remove bacteria which may have gotten into a wound from the bactericidal influence of the tissues and animal juices. 2. Bacteria may travel by continuous growth or in other ways down the sides of a drainage-tube, and so penetrate into a wound which they otherwise would not enter. We have repeatedly been able to demonstrate this mode of entrance into a wound of the white staphylococcus found so commonly in the epidermis. The danger of leaving any part of the drainage-tube exposed to the air is too evident to require mention. 3. The changing of dressings necessitated by the presence of drainage-tubes increases in proportion to its frequency the chances of accidental infection. 4. The drainage-tube keeps asunder tissues which might otherwise immediately unite. 5. Its presence as a foreign body is an irritant and increases exudation. 6. The withdrawal of tubes left for any considerable time in wounds breaks up forming granulations—a circumstance which both prolongs the process of repair and opens the way for infection. Granulation tissue is an obstacle to the invasion of pathogenic bacteria from the surface, as has been proved by experiment. 7. After the removal of the tube there is left a track prone to suppurate and often slow in healing." To these Professor Halsted has added: 8. "Tissues which have been exposed to the drainage-tube are suffering from an insult which more or less impairs their vitality and hence their ability to destroy or inhibit organisms."

But besides increasing the chances of infection, drainage not infrequently gives rise to various post-operative complications. Of these Clark mentions, 1, obstruction of the bowel; 2, fecal fistulæ; 3, vesical complications; 4, post-operative herniæ.

When an abdominal wound became infected subsequently to an operation, it was formerly thought that this result was due to micro-organisms already present, it might be in a pelvic abscess or in the secretions about the uterine adnexa. Undoubtedly this mode of wound-infection may occur, but it should be remembered that in a very large proportion of the cases of pyosalpinx the pus found in the tubes or ovaries is sterile, any organisms which had before been present being dead. This fact has been proved many times by examination of smear cover-glass preparations and the study of cultures made at the time of the operation.

Moreover, in cases in which pus is found at the time of operation we must never forget the *vis naturæ medicatrix*, more especially when we are dealing with the peritoneum. It is a well-known fact, and one proved by the most conclusive experiments, that under normal conditions the peritoneum can dispose of pyogenic organisms in no inconsiderable quantities without the occurrence of peritonitis. Nor must it be forgotten that our drainage does not by any means always remove all foreign fluids and infectious matter, so that in not a few cases its employment will offer all the many disadvantages referred to above, without effecting our main object. Thus Clark says: "By the introduction of the drainage material the peritoneum is handicapped in three ways; 1, the normal peritoneal currents are disturbed, consequently the circulation of fluids and foreign matter toward the diaphragm is retarded; 2, a reactive inflammation is set up about the drain, limiting and impeding the action of the peritoneum; and, 3, within a few hours the general peritoneum is cut off from all participation in the work of absorption by the wall of adhesions around the drain. In place of the natural agencies the work is thrown upon an agent which at best can only remove the fluid from a small pocket. The old illustration cited in favor of drainage, of the gauze wick emptying a bowl of water by capillary attraction, is delusive. The syrup-like serous or bloody fluid, which quickly coagulates and fills up the meshes of the gauze, almost entirely checks the capillary action. A limited quantity of fluid will be removed during the first two hours, but after that the drain acts like a plug by preventing the outflow of fluid, which then accumulates in the dependent pockets. In many instances we have found these encapsulated collections of infected matter within a half-centimeter of a drained tract."

---

* Read in the Section on Obstetrics and Diseases of Women, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

The methods for prevention or the removal of infective material without the employment of drainage may be summarized as follows: 1, a thoroughly aseptic technique; 2, the controlling of all hemorrhage and oozing as far as possible; 3, careful manipulation, so that all unnecessary bruising of the tissues is avoided; 4, a perfect toilette of the peritoneal cavity; 5, the removal as far as possible of infectious foci; 6, the use of irrigations with salt solution; 7, if necessary the reopening and thorough cleansing of the cavity; 8, proper after-care of the patient.

In my clinic we have practically abandoned the employment of drainage in abdominal cases, and for the past seven years we have not used a glass drainage-tube. We have, however, drained by means of gauze on several occasions in which it has been impossible to control the bleeding, and also in those cases in which we have met with a rupture of the bowel during the operation, and it has been an exceedingly difficult task to close the tear.

If symptoms should arise after an abdominal section as the result of the absorption of septic material that has been introduced at the time of the operation, or from remnants of the original diseased foci, we have plenty of time, as a rule, to reopen the abdomen and wash it out again and then if necessary to institute drainage in order to prevent the absorption of more septic material into the general circulation. Such cases are, however, fortunately very rare, and if we employ drainage as a routine in order to anticipate such a condition, we run many risks of infecting the patient. In 222 consecutive cases we used drainage in only one instance, and in this case we punctured and drained through the vagina and also placed one piece of gauze in the lower angle of the incision in the abdomen. A large pus sac was present, which it was impossible to remove; it communicated with the peritoneal cavity and the vagina at the same time. In attempting to open the sac through the vagina an opening was also made into the peritoneal cavity, and since the sac would have drained into the peritoneal cavity we evacuated the contents by the vaginal puncture. Even in this case I do not consider that it was absolutely necessary to have drained through the abdomen.

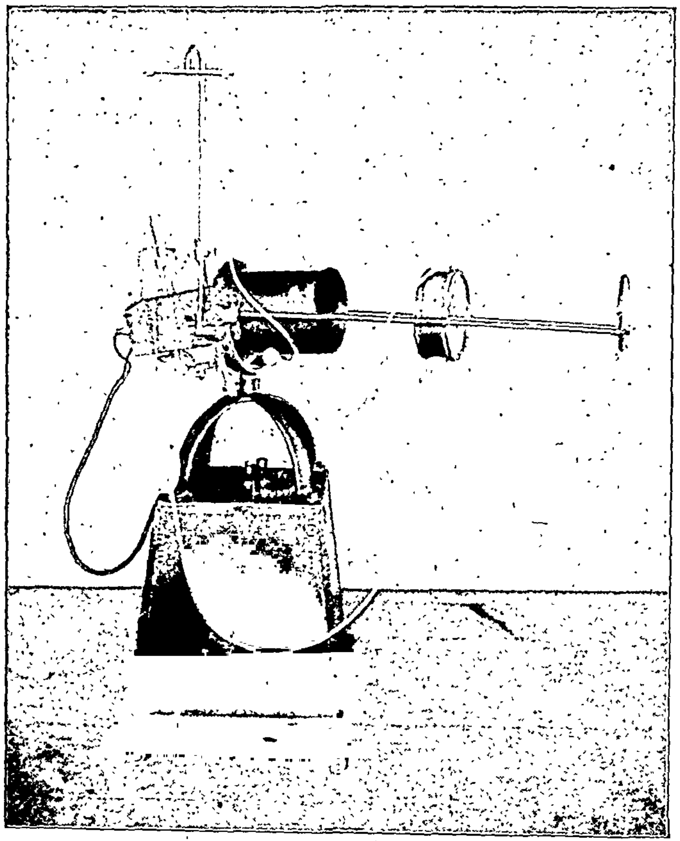
With this single exception—in 222 cases—we have closed the abdomen in every instance, without drainage. In these two series of 222 cases we have met with pus in 65 cases (28 per cent.), varying in quantity from a few cubic centimeters to several liters. After having drained from 15 to 75 per cent. of cases previous to 1893, and for the past seven years having practically abandoned drainage, my observations lead me to emphatically state that patients certainly, as a rule, do very much better if drainage is not used. Not only have the immediate results been better, but the ultimate results, such as the occurrence of hernia and intestinal adhesions, have been avoided.

ACTINOTHERAPY IN CUTANEOUS MEDICINE —A PRELIMINARY COMMUNICATION.

WILLIAM S. GOTTHEIL, M.D.

NEW YORK CITY.

The employment of light as a therapeutic agent is no new thing in medicine. The best term to employ for the treatment in general is Phototherapy. The use of that especial form, the discovery of which has immortalized the name of Roentgen, is generally known as Radiotherapy. Actinotherapy seems to be the most suitable designation for the employment of the ordinary sun or arc light, or portions of their rays. It is to this latter that I desire to call attention.



THE ACTINOLYTE.

To go no further back than the time of General Pleasanton, most of us recollect the "blue glass craze" that swept over the land. Wonderful therapeutic results were attributed to its use; and isolated specimens of the blue glass panes that then appeared in so many windows may still be seen. But Pleasanton and his followers truly saw "as through a glass darkly"; their method was not only empirical, but was developed largely by persons who had no medical knowledge; and it never, therefore, obtained the general recognition of the profession.

The bactericide action of light is now an established and well-known fact. Cultures of many virulent and pathogenic microbes die in a short time when exposed to properly concentrated light. Axel L. Larsen[1] has lately gone over the ground again with the pus organisms, the colon and typhoid bacilli, etc., and has endeavored to determine with exactitude the time required to weaken and destroy them with given concentrations of light.

---

[1] Mittheilungen aus Finsens Medicinske Lysinstitut, 1900.

But this is by no means its only action, and probably not even its chief one. It irritates the cutaneous nerves and so affects the central nervous system. It increases the oxidation processes in the cells and the amount of hemaglobin in the blood. The heightened tissue metamorphosis is possibly the factor on which its future therapeutic application will be based.

The ordinary phenomena of transillumination show that light penetrates the skin. Contact photographs have repeatedly been made by means of light that has passed through the human body, notably by Kime, of Fort Dodge, and H. L. Mason, of New York. Glass tubes containing sensitive silver salts have been introduced under the skin of animals, and have shown the characteristic effects of light penetration on removal.

To Niels R. Finsen of Copenhagen, however, belongs the credit of developing the light treatment and placing it upon a scientific basis. Since the time, now several years ago, when he recorded the good effects that he had gotten in variola from the employment of red light, he has been an indefatigable worker in this field; and to-day his Actinotherapeutic Institute in Copenhagen has a world-wide reputation and enjoys the active support of the Danish government.

I shall leave out of account, as foreign to the object of this preliminary paper, the work that has been done in other than dermatological fields with the new treatment, or an account of the various forms of apparatus that are employed. Suffice it to say that Helm,[2] Gerson,[3] Morris,[4] and Finsen, Bie and their collaborators in numerous publications have employed it in many varied dermatoses with a large proportion of good results. Besides lupus and the various dermal tuberculoses, in which it is possibly destined to be the treatment par excellence, it has been used in lupus erythematosus, psoriasis, epithelioma, acne vulgaris, rosacea, alopecia areata, eczema, ringworm, contagious impetigo, and various ulcerations, with success.

Either sunlight or the electric arc can be employed; but the former is too uncertain in most parts of our country to be relied upon. The chemical or actinic rays of the more refrangible end of the spectrum are the elements from which therapeutic effects may be expected; and we have fortunately in the electric arc a source of light which is accessible in all our large centers at any time, and which is especially rich in them. Sunlight is cheaper, of course, but it is only in regions like California or New Mexico, where it can be relied upon for a great part of the year, that the expense of installing a sunlight apparatus would be warranted. The arc light can be employed on cloudy days, or in the evening, and this leads me to mention and dispose of one apparent disadvantage of the process.

The actinotherapeutic treatment takes time; of that there can be no doubt. But I am convinced that it does not even now require the hourly sessions every day which Finsen gives his patients. Were that the case, then, no matter what its advantages, it would have to be relegated to institutions where the necessary elaborate arrangements for the simultaneous treatment of a number of patients could be made. Increase of the amperage employed, and the reflexion and concentration of all the available rays upon the area to be treated has enabled me already to reduce it very materially, and I have no doubt that further progress in that direction will very shortly be made. I now give half-hourly sittings every other day. The question is solely one of actinic light intensity.

I employ the instrument manufactured by a firm of this city, and called by them the Actinolyte. It consists essentially of an arc light with the necessary arrangements for automatic action, enclosed in an iron hood. In front of the arc is a double convex condenser, adjustable for focusing purposes by means of a rack and pinion. On rods that project in front from each side of the hood is a double convex focusing lens, also adjustable. By means of these condensers a circle of light of any size can be readily obtained; of course the smaller it is the more intense is the illumination. The hood is swung in such a way that it can be raised or lowered, and swung laterally and vertically, thus making it possible to project the light spot with exactitude upon the area that is to be treated.

On the front bars and between the hood and focusing lens is a cell for the purpose of containing the fluid to cut off the heat rays. This can be filled with distilled water, or methylene-blue or alum solution, or it may be connected with the two water-bags for which arrangement is made, so that a continuous stream of heat-absorbing fluid may flow through the cell. So far I have found plain cold water without continuous flow quite sufficient to prevent any unpleasant heat effects from the concentrated light.

The base of the instrument contains a suitable rheostat, with a selector on top. Either the continuous or alternating current may be employed, and from 25 to 55 amperes of current can be used. The candle power varies, of course, with the amperage. With a concentrated circle of light it runs from 20,000 to 60,000.

I am not prepared as yet to make a definite statement of the results obtained with the treatment, save in two cases. In one extensive lupus vulgaris they promise to be brilliant. The one area that has been treated, some 2 inches square, presents a marked contrast to other locations where the disease is progressing. It is almost white, only two or three lupoid nodules remain, and they are disappearing. This has been accomplished without ulceration, or even inflammation, the process has been entirely one of interstitial absorption. All the other areas are characteristically infiltrated and scaling. The patient has had absolutely no other treatment.

The second case was one of obstinate tertiary syphilitic ulceration of the leg. The light had an apparently good effect in stimulating the indolent glazed ulcer, so that it is now nearly healed, after resisting other internal and local treatment for weeks.

The advantages of the method are: 1. It is eminently conservative. It causes no radiodermatitis, ulceration, or loss of hair, such as too often, though sometimes necessarily, occurs under the Roentgen treatment. I do not know of the record of any serious trouble from its employment. Finsen rightly lays stress upon this point, and to dermatologists it is of especial importance, since many of the affections that they are called upon to treat occur upon the face. 2. It is entirely painless. This is a great desideratum, more especially in dealing with women and children. 3. It is effective. New as the method is, there is already concurrent testimony from a sufficient number of competent observers to demonstrate that we possess a powerful therapeutic agent in concentrated light.

[4] British Journal of Dermatology, August, 1900.

Leaving to others the study of the effects of actinotherapy in the general conditions and affections of the internal organs in which it may prove useful, it is to be presumed that by dermatologists it may be employed in the various skin affections that are dependent upon micro-organic or parasitic infection, or where increased tissue metamorphosis is a desideratum. Lupus vulgaris, lupus erythematosus, mycotic eczema, trichophytosis, favus, impetigo, furunculosis, tuberculosis cutis, epithelioma, mycosis fungoides, blastomycosis, actinomycosis, and similar affections are the diseases in which it is likely to prove useful.

144 West Forty-eighth Street.

A NEW OPERATION FOR REMOVAL OF CANCER OF THE RECTUM.*

MATTHEW D. MANN, A.M., M.D.
BUFFALO, N. Y.

The situation of the rectum, placed as it is deep in the bony pelvis, makes it very difficult of access for surgical purposes. Thus far, three routes have been proposed for its removal. As yet no definite decision has been arrived at as to which of these is the best. Each has its advantages and disadvantages, and each has its advocates. The posterior operation, as Murphy very properly says, is difficult, dangerous, and in many respects unsatisfactory; the mortality, he quotes as 21.2 per cent.

The latest proposal for professional favor is that made by Dr. J. B. Murphy.[1] His operation is the resection of the rectum through the vagina. Although the idea of operating by this route is not original with him, yet for the perfected form of the operation we must give him the credit. Murphy's operation seems to have many advantages over the transsacral method. There are no objections attending it except the technical difficulties. These must be very great, but differ, no doubt, with different cases. In an old nullipara they must be almost insurmountable; but when the vagina is roomy and the growth quite low in the rectum, it is probably the best operation which has yet been suggested.

Curiously enough, nobody has yet proposed the resection of the rectum from above.[2] The nearest approach to it which I have been able to find, is the operation done by J. Price, in which, after removal of the neoplasm, he has united the cut end of the rectum with the vagina. This necessitates defecation through the vagina without any sphincter to give control.

The plan which I have to suggest is suitable for cases in which the growth is too high to be easily reached through the vagina, and has the great advantage of leaving the sphincter intact and the movements of the bowels in their natural course uninterfered with. The possibility of the operation depends on the fact that, by the aid of the Trendelenburg position, the pelvis can be emptied of all the intestines, even the rectum and the sigmoid. This gives plenty of space to work, and makes the operation possible.

I was first led to do it by a mistake in diagnosis. A patient came to me with a small mass behind the uterus. She complained of some difficulty and pain on defecation. I thought the mass, which was freely movable, was a prolapsed ovary, as it was about the right size, and that the pain in defecation was caused by the pressure upon the ovary. I, therefore, opened the abdomen with a view to the removal of the ovary; but, on passing my finger into Douglas's pouch, I was surprised to find nothing there. While palpating the parts, I discovered the growth in the rectum. I determined at once to resect, believing that the growth was probably malignant and the cause of her trouble. After removing the growth, I found very great difficulty in sewing together the cut ends of the rectum, but finally succeeded quite easily in placing a Murphy button. Then, with one finger in the rectum and the hand in the pelvis above, I had no trouble in uniting the two halves of the button.

The patient made an uninterrupted recovery, and was examined some time after her return home, and found to be in a perfectly healthy condition.

An account of this operation was published in the *American Medical Quarterly* for 1899, as well as the history of two other cases. In that paper I drew attention to the abdominal method of attacking carcinoma of the rectum, but it does not seem to have attracted any notice. I shall,therefore, draw somewhat upon what I have written before, especially upon the reports of cases.

The second case on which I operated was one of stricture of the rectum due to inflammatory exudate. I had previously resected the patient's small intestine, and one year later she came with a recurrence of the old symptoms. At the time of the first operation, I had noticed inflammatory trouble in the pelvic cavity, but her condition did not warrant its removal. I diagnosed stricture from this cause, and proceeded to resect the rectum at the very bottom of the cul-de-sac, exactly as in the case before. In this case the button came away on the eleventh day, and convalescence was complete. The patient has remained well up to the present time, a period of three years.

My next case was not so fortunate. There was a large mass behind the uterus, half as large as one's fist. On opening the abdomen, I found the mass adherent to the posterior wall of the pelvis. It was easily loosened, and in the Trendelenburg position was cut away, both above and below, and four inches of intestine resected. No difficulty was found in pulling up the rectum and in placing a Murphy button. With the finger of an assistant in the rectum, to steady the lower button, the two halves were easily pushed together. A glass drainage-tube was placed from above, the pelvis having been previously thoroughly washed out with salt solution.

The patient did well for four days. During my absence from town attempts were made to remove the button, but were unsuccessful. Following this the patient developed a general peritonitis, from which she died.

Since this case, I have had two others, both of which were successful. In one of them the growth extended below the posterior edge of the cervix uteri. In order to get it out, it was necessary to cut the peritoneum at the bottom of Douglas's pouch, and to pull the rectum up above its peritoneal investiture. The difficulties of placing the lower half of the Murphy button were greater than in the other cases, but did not offer any insurmountable obstacles. In this case the disease recurred within eight months.

---

* Read in the Section on Obstetrics and Diseases of Women, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

[1] Phila. Med. Jour., Feb. 23, 1901, p. 383.

[2] The operation of W. R. Pryor (Gyn. Trans., 1900), although done partially through the abdomen, is for carcinoma of the vagina and rectum, and is, therefore, applicable to a different class of cases.

The last case was about the same as the previous one, the carcinoma being easily reached by the finger in the rectum. The patient remains well at present, after a period of five months.

The technic of the operation, as I have now developed it, is as follows: The rectum and vagina should first be thoroughly cleansed. The abdomen being opened, and the patient placed in the Trendelenburg position, the rectum just above the growth is clamped with a long hemastatic forceps and cut off. The sigmoid flexure and rectum are then pulled out of the pelvis, the meso-rectum being slightly cut away if necessary. This leaves the pelvis entirely free for manipulation of the lower end. If the growth be above the peritoneal investment—that is, above the bottom of Douglas's pouch—it should be cut off low enough to secure all the malignant tissue. The diseased portion is then entirely removed, all bleeding vessels being tied. One or two large arteries usually show themselves at this point. The lower end of the rectum is next seized and drawn up, care being taken not to injure it, as it is very easily torn. It is surprising how much this can be pulled up, and how easily it can be manipulated. It has no peritoneal envelop. There is no difficulty in getting plenty of slack to pull down that portion of the rectum above the resection, even after several inches have been removed, for, as Murphy has correctly stated, "the normal position of the sigmoid is in the pelvis, and not in the left iliac fossa, as is generally supposed."

With a short, round, curved needle—the Emmet vesicovaginal fistula needle is the one I use—a silk suture can be run around the end of the gut. The Murphy button is then placed, the piece with the long projection being preferably put in this position. After this step is completed, the other end of the button is placed in the upper cut end of the intestine and the two are brought together. To accomplish this, the lower end of the button must be held by one or two fingers of one hand in the rectum.

If thought advisable, drainage through the posterior cul-de-sac into the vagina may be made, and a rubber drainage-tube placed in this position. In my last case I resorted to this expedient, and believe that it is a valuable addition to the technic of the operation. The abdomen is closed in the usual way.

If the growth extends below the bottom of Douglas's pouch, the peritoneum must be cut close to the uterus, and the incision carried around the rectum. The rectum, with the portion of peritoneum adherent, can then be pulled well up and incised below the growth. The deeper the growth the harder it is to place the Murphy button; and if the growth extends down as low as the level of the external os, then the difficulties will be found to be very great. This, however, should not weigh, because all operations on the rectum are difficult, no matter what the way of approach may be.

I use the Murphy button for the reason that the making of a tight joint by sewing down in the bottom of the pelvis I find to be very troublesome. It may be objected that where the button is placed in the rectum deprived of its peritoneal envelop, union will not take place. I find, however, that this objection is not valid, as in three of my cases the button was applied to the portion of the rectum below the resection, where it was denuded of peritoneum, and yet two were successful.

The cases in which this operation would seem to be especially indicated are those in which the growth is all above the bottom of Douglas's pouch, though I would not restrict it wholly to such cases. The nearer to the brim of the pelvis, the stronger are the indications for the operation. In one case—a man—I resected in the sigmoid, using the button as before. This, however, I do not count among the cases of resection of the rectum.

Senn, in his work on intestinal surgery, states that resection in the bottom of the pelvis is impossible, and that, for the same anatomic reasons, lateral anastomosis can not be made. My cases would seem to show that Senn's estimate of the difficulties of resecting deep in the pelvis is too high. The Trendelenburg position and the button have made a great change; without them the operation would not be feasible. The usual objections to the button certainly do not count here, as in most cases it is within easy reach, and can be extracted if it does not come away of itself. In my last case I was obliged to remove it, as it seemed to settle into a kind of a pocket and to show no disposition to come away, the bowels, however, moving freely through it.

An instrument which I have found to be of great use in this, and in other operations where the patient is put in the Trendelenburg position, is the self-retaining retractor. In a favorable case, with a moderately long incision, the way in which the interior of the pelvis is made accessible to sight and touch is remarkable.

The Cleveland operating-table is another adjunct which is a great help. This table is so arranged that the operator has easy access to the vagina and rectum while the patient is in the Trendelenburg position.

My friend, Dr. Eugene Smith, surgeon to the Buffalo Charity Hospital, after having seen me operate, has performed the operation once, on a man, and reports that he met with no special difficulties, and that he is pleased with the procedure.

If called upon to limit the indications for this operation, I would say, do Murphy's operation when the lower edge of the growth is less than about one and a half inches from the inner edge of the anus, and in all other cases open above and resect.

I do not claim that this operation is easy under the best of circumstances, but what operation for carcinoma of the rectum is? However, I do maintain that it is feasible and that it gives the best chance to make a clean and complete removal of the neoplasm, and will, therefore, in proper cases give the best attainable results.

DISCUSSION.

Dr. Henry O. Marcy, Boston—I have had no experience in the resection of the lower bowel through an abdominal section. In 1893 I resected the sigmoid for cancer, uniting the segments by a large-sized Murphy button. It came away the twelfth day. I removed a portion of the sacrum and entered the peritoneal cavity from below. The patient died the following year from a return of the disease. This was, so far as I know, the first time the Murphy button had been used in the resection of the lower bowel. My friend, Dr. H. O. Walker, of Detroit, had suggested to me this method of approximation.

Dr. J. Wesley Bovee, Washington, D.C.—I heard Dr. Edebohls read his paper on this subject. The operation was done in a case of cancer of the rectum associated with a pregnant uterus. The operation was preceded by an abdominal hysterectomy, and I would suggest in doing this work in women that a hysterectomy will in most cases be advantageous, inasmuch as it gives the larger field of operation. Dr. Edebohls' case was a successful one. I believe Dr. Mann's conclusions are correct. These cases where the cancer is fairly well up do better by being removed from above than from below.

Dr. Mann, closing the discussion—The subject can not be discussed, as most men have had no experience with it. I think

Dr. Edebohls' suggestion may be of service in some cases by giving a larger field of operation, but in a case of a small uterus I do not think it would be sufficiently in the way to make its removal necessary. A pregnant uterus would, of course, be very much in the way.

THE ACCIDENTS AND COMPLICATIONS OF PELVIC SURGERY AND THEIR TREATMENT.*

J. B. DEAVER, M.D.,
PHILADELPHIA.

The necessity for a thorough knowledge of the pelvic viscera, their topographical relations, and the pathology of their diseases, is of paramount importance in dealing with the diseased organs intelligently.

The ordinary procedures of complicated pelvic operations may cause so much damage that even the expert may be taxed to the utmost in dealing with them, e. g., the enucleation of an adherent intraligamentary cyst, or where one or other ureter is involved, a careful dissection may be necessary to free it. The ureter may be damaged to the degree that repair can only be accomplished by an anastomosis, or implantation; or where there is troublesome bleeding, for the control of which the uterine arteries may have to be exposed.

The common occurrence of adhesion, the result of inflammatory process involving the pelvic viscera, are of sufficient importance to call for our careful consideration.

The character of the adhesions vary; some are easily separated, while the old and organized ones will call for considerable manipulation to liberate them.

In this connection, the writer begs to state that only by thorough work can the patient be expected to recover, by which, I mean, get permanently well and remain well. The bane of the abdominal surgeon is the formation of post-operative adhesions, therefore it goes without saying, the fewer left at operation, the better the patient's chances against post-operative pain, etc. The ability to do better, safer and more thorough work by the abdominal than by the vaginal route can not be better demonstrated than by raising the question of the importance of disposing of all adhesions in any given case. The vaginal operation has been spoken of as "the dismal swamp procedure," and rightly, too, I think.

I fear that too many operators are content with simple removal of the lesion. This is only makeshift work. A true artist does not consider a piece of work done until finished, that is, until the structures involved in the disease have been returned to their normal condition, or as nearly so as finished surgical technique can accomplish it. The evacuation of a collection of pus in the pelvis by vaginal puncture, or the evacuation of an appendiceal abscess by simple incision, or the removal of stones from the gall-bladder, leaving a stone or stones in the common duct, can in but few cases be sanctioned by the surgeon. The thorough liberation of adhesions, the covering in of abraded or torn surfaces by peritoneum, I can not be too strong in advocating, for I see many patients who suffer from incomplete work, to conscientiously do otherwise. To finish up a case by undoing the bad work of a previous operation speaks for itself. I am sure, too, that many cases which are subjected to incomplete operation had better not have been operated at all, as the last state is worse than the first. The practice of filling the abdominal cavity with normal salt solution, does not, in my judgment, prevent adhesions, as it is too quickly absorbed.

The pelvic wall, floor, the rectum, sigmoid, cecum, vermiform appendix, small bowel, omentum or mesentery, bladder, ureter and uterus may be involved singly, or they may all be included in an inflammatory mass or in conjunction with and adherent to a tumor.

The breaking up of adhesions involving the pelvic walls or floor does not entail as great a liability to serious injury as is likely to occur when freeing the viscera; I will, therefore, merely mention the method employed in dealing therewith. The parts having been thoroughly exposed, a point is selected which seems to offer the best point to attack the mass of adhesions and an attempt is made to peel them off, which, in some instances, is accomplished without much difficulty. In others the mass can only be broken through after considerable force has been exerted. Again, it may be found necessary to divide the adhesions with a scalpel.

The terminal portion of the sigmoid flexure, but more particularly the rectum, both from the depth of the latter and its small range of mobility, offer great difficulties, in the process of enucleation, from a mass of adhesions or from a growth, and owing to its fixed position does not permit the same freedom for manipulation as does the sigmoid flexure above it.

In adhesions to these viscera an effort is made to find some point of attack, as in separating adhesions of the wall or floor of the pelvis and working gently away from the imprisoned bowel, which at times, even with the utmost caution observed, is torn, owing to its softened condition, from the inflammatory process. If the bowel has been torn, or the integrity of its wall impaired, the rent should be closed at once, or if too large to permit of this, the opening must be temporarily plugged with gauze until the remaining portion of the operation is completed, when the gauze plug is removed and the opening packed off from the peritoneal cavity with gauze, the gauze end being brought out at the lower part of the abdominal wound, thus favoring the establishment of a fecal fistula. It has been suggested under these circumstances to divide the bowel across and invaginate the proximal end into the distal end, retaining it by a continuous Lembert suture. This I have practiced when the distal end of the bowel was not softened to a degree which would render the procedure useless.

The sigmoid, like the rectum, is liable to be included in an inflammatory mass, but not to the same extent. Adhesion of this portion of the alimentary tract occurs in connection, most commonly, with pelvic tumors, fibroids of the uterus, ovarian or parovarian cysts and some cases of pyosalpinx. Extensive injury of the sigmoid flexure or of the mesosigmoid should not embarrass the operator, as resection and end-to-end union is easily done. The omentum, on account of its wide area of distribution, will be found adherent in a large percentage of the cases requiring abdominal section. It is often found surrounding a purulent collection, or forming a part of its limiting wall, or spread out fan fashion and attached to a pelvis mass. It is, therefore, safer to ligate the adherent structure previous to its separation, with preferably silk ligatures. The omentum is not ligatured en masse, but in sections. In dealing in this manner with the great omentum in elderly people, where the blood vessels have undergone senile change;

---

* Read in the Section on Obstetrics and Diseases of Women, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

it is of the greatest importance to include in the ligature but small sections, thus lessening the chances of secondary bleeding.

The small intestine and the mesentery are frequently found adherent to a pelvic mass. This is particularly so in the acute inflammatory diseases of the Fallopian tubes, and of the vermiform appendix. It is not unusual to find the small bowel and its mesentery forming a part of the abscess wall, especially in the iliac fossa.

When the adhesions are filamentous they may be broken up with impunity; where, however, they are spread out over a broad surface, as is seen when extensive plastic exudate has become organized, then the dissection must be carried out with care, to avoid tearing the bowel.

Injury to the peritoneal coat of the bowel does not, in itself, present any formidable condition, but where the muscular coat has been torn an effort should be made to suture the torn coat together, providing that the caliber of the bowel will not be impinged upon too much.

The bladder when in its normal relation is frequently found adherent to the omentum, and presents but few difficulties in the disposal thereof; ligatures applied successively one after another until the omental mass has been securely tied off and removed, will dispose of this complication.

A bladder adherent to the prolapsed fundus of a uterus and adherent to some other pelvic viscus will at times present a difficult problem to solve, and a tear under these circumstances is more likely to occur than under any other condition. If the peritoneal coat is torn a few interrupted sutures will close the torn surface; if the cavity of the bladder has been opened a series of fine silk sutures closely applied, including the peritoneal and muscular coats alone, will, in the majority of instances, suffice. After the repair of a complete rent in the bladder wall, the organ should be distended with a boric acid solution, or with normal salt solution, to determine if the wound has been securely closed.

The displacement upward, to which the bladder is liable in the presence of a large growth or cyst, makes it possible to injure that viscus in making the abdominal incision.

The ureter, unlike the other occupants of the pelvis, being behind the peritoneum, is not liable to adhesion, except from subperitoneal growths, and is, therefore, not nearly so likely to be damaged. It is most often damaged in the course of an operation for the removal of a large uterine fibroid, and particularly in the application of the ligature to the uterine artery. It is also liable to injury in the process of enucleation of a large parovarian or intraligamentary cyst or growth, particularly if the ureter overrides a portion of the tumor, and is masked by a mass of superimposed lymph. Preliminary catheterization aids in avoiding this accident.

The uterus and its adnexa form the origin of the bulk of the pelvic tumors that attain sufficient proportions to produce distortion of the other pelvic viscera, or occasion serious complications in the attempt at their removal. The complication incident to tumors of the uterus may be summed up into those which are due to the growth in the uterus, to pyosalpinx, ovarian or tubo-ovarian abscess, suppurating dermoid, a sloughing fibroid, or even suppuration within the uterus itself.

Peritonitis in association with fibroids is rare in comparison to that of ovarian tumors and the inflammatory affections of the uterine appendages. Following an attack of peritonitis, there may be, and frequently is, an agglutination of the pelvic viscera, and the first of these to receive the benefit of the inflammatory process is usually the tubes and ovaries, which become tied down, either to the uterus or to the pelvic walls or floor. The difficulties encountered in delivering some large growths are familiar to all, and in many instances this is occasioned by the adhesion of the tubes and ovaries to the pelvic wall or floor, and it is often impossible to deliver the tumor into the wound until they have been freed. In addition to the adherent tube and ovary, on the right side, an adherent appendix or cecum may add to the difficulties of the case, while on the left side the same may be true of the sigmoid.

If, in connection with the above complications, pus is present, it is only after the most careful walling off of the peritoneal cavity that any attempt should be made to remove the uterus with its tumor.

In addition to the bowel complications, the ureter will be found displaced in some instances to the degree of overriding a part of the fibroid, tumor or inflammatory mass. If the ureter is recognized before an attempt is made to deliver the enlarged uterus, or prior to the ligation of the ovarian vessels, it will be a very simple matter to dispose of the peritoneum so as to free the ureter and lift it out of the way to a place of safety until the fibroid uterus has been disposed of.

The vermiform appendix when adherent to the uterus is disposed of by the removal of the appendix, excising it from the cecum and closing the opening in the bowel with continuous Lembert sutures.

The removal of cysts, and inflammatory masses, while presenting difficulties in the shape of extensive adhesions to the pelvis and to adjacent viscera, do not offer the same difficulties, owing to the fact that a portion of the growth, if not malignant in nature, can be left behind if there is any danger of doing too much damage to the structure to which it is attached. When a large cyst of the ovary is intimately adherent to the bladder, bowel, or to the pelvic wall, and there is danger of tearing the bowel, bladder or ureter, a small portion of the cyst wall can be left behind, searing its cut surface with the cautery to prevent oozing from its cut surface.

Malignant growths of the uterus and its adnexa, or of the alimentary tract contained in the pelvis, or of the bladder by the extension of the malignant process beyond the primary seat of invasion are inoperable cases.

The most common complications of rupture of an extra-uterine gestation have been, in my experience, hemorrhage, adhesions and appendicitis. Of the former much can not be said, other than it is necessary to rapidly discover the bleeding point and secure it with a ligature. Upon opening the abdomen of a case of ruptured extra-uterine pregnancy large quantities of blood and clots make their escape from the incision, and as rapidly as possible the affected tube should be seized, brought into sight and tied off, subsequent to which the blood and blood clots can be removed. If the rupture has occurred some time previously and the mass has become adherent to adjacent coils of intestines, then as much of the mass can be removed as will not interfere with the integrity of the bowel. If the placenta has become firmly attached to the intestines it is safer not to attempt to remove it, but to wall it off with gauze and allow it to separate spontaneously.

When appendicitis and extra-uterine pregnancy are found present together the latter usually involves the tube of the right side. It is only in the presence of a sepsis that much danger can accrue from the combined lesion. Here the danger of an infection of the general peritoneal cavity can easily take place, and only the most careful protection of the general peritoneal cavity by gauze packing, isolating the right iliac fossa completely, will secure immunity from infection.

Of all the serious pelvic conditions to which the surgeons are brought face to face, purulent collections in the pelvis; especially those of appendical origin, are, in the writer's mind, the most dangerous and trying ones to deal with. The immediate danger to which the patient is subjected, and the liabilities of remote consequences, make this probably the most important question in abdominal surgery to-day. To decide upon the best means of preventing infection of the peritoneal cavity and the proper disposal of the pathological lesion requires that the surgeon not only possess the utmost skill, but the greatest experience in this class of work.

The source of abdominal hemorrhage following the removal of some pelvic lesion is at times difficult to discover and to control; if, however, the intestines have been kept free from the field of operation by gauze packing, there should not be very much trouble to discover the bleeding points and secure them with ligatures.

The points where hemorrhage is most likely to take its origin are, from the omentum, the ovarian, uterine, the appendical and the mesenteric vessels.

The most serious complication of the removal of uterine fibroid is hemorrhage, therefore, why one of our most prominent abdominal surgeons clings to the extraperitoneal treatment of the stump. Myomectomy, while applicable to a few cases, is doubtless open to the same objection. We will agree that post-operative peritonitis ranks highest in the fatality of pelvic operations. In the absence of infected lesions peritonitis should not occur, yet with all care it unfortunately continues to cost a small percentage of lives. Simple, thorough technique, including the use of rubber gloves by all who assist at the operation, offers the patient the safety against this dangerous complication. The gloves should be worn throughout the operation and not taken off when a difficult part of the operation is reached.

A recital of the accidents and complications of pelvic surgery would be incomplete without touching upon the danger of and accidents due to operations on the uterus per vaginam consequent to a dilatation and curettage or to a repair of a lacerated cervix.

Before any operative procedure on the uterus or cervix is attempted there should be some very strong indications calling for its performance, and what is of greater importance, the absence of any pathological condition of the tubes or the ovaries must be eliminated. The existence of a salpingitis, a pyosalpinx, or of adhesions, would be the strongest contraindication to any measures for operation per vaginam, unless an abdominal section was contemplated in connection therewith, so as to be able to deal with the intra-pelvic conditions at the same time.

The possibilities of introducing a peritoneal infection by means of the comparatively harmless procedures which the average family doctor and occasional operator considers his province, dilatation, curettage, or a repair of a torn cervix, can only be appreciated by those who see the numerous invalids and physical wrecks consequent upon these very harmful measures.

Let us consider the accidents which may occur in the simple operation of curettage: Perforation of the uterus, the lighting up of a salpingitis, the breaking up of adhesions and the ever present danger of peritonitis. Let me state here that the liability to perforation of the uterus, even in the hands of the most expert, is great, and that in some instances this occurs so unexpectedly that a loop of bowel may either be torn or dragged down into the uterus before a perforation is even suspected. I have seen several instances of this kind, where patients were brought to the hospital with severe uterine hemorrhage and a loop of intestine found prolapsed into the cavity of the uterus, calling for an immediate abdominal section to restore the bowel to the cavity and to repair the perforation of the uterus.

The importance of observing thorough asepsis in any operation per vaginam is imperative if we wish to eliminate the infections. When we consider the great opportunity for infection from an active or latent gonorrhea, from the presence of the many micro-organisms found in the uterus, and the possibility of opening up new fields for their activity as a result of the exposure of fresh surface by the use of the curette, it is remarkable that there are not more cases of salpingitis after this dangerous operation. The mucous lining of the Fallopian tubes is continuous with the lining membrane of the uterus, and the same condition often exists in the tubes as is found in the uterus; it is, therefore, not only a useless procedure but a most harmful one in most cases, to curette the cavity of the uterus without being able to correct the disease in the Fallopian tubes. The practice of plugging the uterine canal with gauze for purposes other than drainage is vicious and is a prolific source of salpingitis.

The same objections and dangers are attendant upon dilatation of the cervix uteri as in curettage. This operation has a limited field of usefulness and is indicated only in those cases of dysmenorrhea which are not associated with tubal or ovarian disease, pelvic inflammation or of fixation of the uterus. The operation is a disappointing one in many instances, and the dangers of lighting up a latent pelvic lesion so great that I would class this as a dangerous procedure, and not to be attempted by those who are unfamiliar with ordinary pelvic technique, on account of the necessity for thorough surgical cleanliness and the ability to recognize the various pelvic lesions, whether acute or latent, which contraindicate the operation of dilatation.

The treatment of a lacerated cervix, to my mind, calls for as great a display of good judgment and skill as does any of the major operations on the pelvic viscera. Here again we have the same possibilities and risks to contend with as in the operation of dilatation and curettage, viz., the lighting up of a salpingitis, of a peritonitis or some peri-uterine pelvic inflammatory process. In the absence of any contraindications from the pelvic viscera, tubes or ovaries, and with the condition of the laceration of the cervix warranting interference, the operation, being done under strict aseptic precautions, is generally under these circumstances not unattended by danger, if we are not careful to leave sufficient room in stitching up the laceration to permit free drainage of the uterine canal, and I may add that this is one of the most fruitful sources of subsequent salpingeal disease.

DISCUSSION.

DR. FRANK CARY, Chicago—I wish to ask the Doctor whether he said that he did not believe that there are any cases of women who have borne children and have not a lacerated cervix.

Dr. Deaver—I did.

Dr. Cary—Then I wish to say that either the gentleman has had a very limited experience, or his patients have been exceedingly unfortunate in their obstetricians.

Dr. Philander A. Harris, Paterson, N. J.—I have established to my own satisfaction that a certain number of cases with pus in the pelvis can be operated on more easily and cured more rapidly per vaginam. It is not easy to judge just what cases can be most safely operated on from below, but those who do a great deal of vaginal section work for puerperal sepsis are in a better position to judge. Occasionally you find exudates which appear rather suddenly and which may, or may not fluctuate, and yet, if you make an incision in the cul-de-sac, you effectually reach and discharge the pus, and the patient is symptomatically cured. We know that unless our incision has been properly made, we have afforded our patient only temporary relief. No person who has not employed this method, and who has not had a great deal of experience with it, has any right to condemn it. He who has had experience with it will recommend it. I am well satisfied that I have lost two cases by operating from above, which I might have saved by operating by the vaginal route. One, a case of pelvic hematocele which I saw five weeks after the rupture of a tubal pregnancy, had a clot which was so firmly organized that I could not distinguish it from a fibroid tumor, which the pelvis also contained. I operated by suprapubic section, and opened the hematocele, in the interior of it were two or three ounces of pus. That patient died very quickly from sepsis. If in that case I had made only a vaginal section, I would have had no trouble in recognizing the conditions present. I would have reached the cavity of the hematocele, discharged it through the vagina, stopped the considerable sepsis, and she would have been afforded a good chance of getting well.

Dr. Frank Warner, Columbus—I understood Dr. Deaver to say that many cases of lacerated cervix are operated on which should not be. As highly as I esteem Dr. Deaver, I must say that this is vicious teaching. We are apt to go home and leave many of these cases alone that should be operated on. Dr. Deaver has had a wonderful experience in abdominal surgery, but I question whether his experience has been broad in obstetric work. What harm do these operations do? They are very slight operations, and if they do not harm, why should we not restore the cervix to its original condition? He makes one exception, the development of cancer. I would like to ask him what case of appendicitis can he say will not develop into a cancerous appendicitis, and equally so which of these cases of lacerated cervix is going to develop into a cancerous cervix? Is it only those cases having a cancerous or hereditary tendency? I take issue with the Doctor, and say that these cases should be operated on; they should be restored to their normal condition. We can not possibly do any harm in operating on these cases.

Dr. Edwin Ricketts, Cincinnati—Dr. Deaver speaks of the vaginal route as a dismal swamp, and that vaginal puncture is not a surgical procedure. I wish to say that all he needs is more light in his "dismal swamp," and he will do better work. Take most of these post-delivery cases, in which there is an infection and accumulation of pus within the pelvis, with high temperature, rapid pulse, and you do not see that patient until rather late; I want to say that if you drain according to the older obstetricians, and give that patient relief by the vaginal route, you give her a better chance for her life than by operating by the abdominal route. There is something that the older obstetricians taught us that we are getting a little too far away from, and that is, to deal with pus as in the manner described. I say this, with all due respect to the general surgeon, who claims that he is better able to handle pus in the pelvis than the gynecologist and abdominal surgeon. I can call to mind several cases in which vaginal puncture was resorted to, a primary procedure, and those patients went on to recovery and in time bore children. Many similar cases are on record, and will help us out in this difficulty of abdominal versus vaginal incision. I recollect two cases in the earlier part of my work, when I was an enthusiast over the abdominal method, and they did not recover. Since I have adopted the plan of vaginal puncture in selected cases, I have had better results. If necessary, you can follow with the abdominal operation as a secondary procedure. This is the little light which my friend Deaver needs. He is very positive in his assertions. There is a happy medium which none knows better than the older obstetricians. If there is pus frequently it is better to let it out by the vaginal route, and do anything that may be necessary later on. Often no other procedure will be necessary.

As to drainage after abdominal section, if you open the abdomen and find the pus sac with thick walls, you can enucleate it, but if the walls are thin and fragile, it is better to puncture from below and drain rather than enucleate it through the abdominal incision. By this you prevent the extending of the infection. Extra-uterine pregnancy is always best dealt with through the abdominal incision.

Dr. W. O. Henry, Omaha—Dr. Deaver is always very positive, but I think he is too dogmatic. His statements will not always bear careful investigation. The matter of drainage is one of them. The man who opens the abdominal cavity in these acute cases will lose a large majority of them, whereas the man who first opens by the vaginal route will save nearly all of them. He says that all women who bear children have a lacerated cervix. A large proportion of them do not have a lacerated cervix. When he says that not one in fifty of those who have lacerated cervices needs to be repaired, he is greatly mistaken. It is true, some do not need it, but the large majority of them ought to be repaired. We know very well that a large majority of women with cancer of the uterus have it begin in a lacerated cervix. When it starts there, it rapidly spreads out into the broad ligaments. The latest statistics seem to show that not even 5 per cent. of them can be permanently cured, even if operated on. Women who have had a lacerated cervix are more liable to cancer than those who have not, and we owe it to our patients, our profession, and to society, to repair these cervices before cancer begins, and thus prevent its development.

Dr. Andrew Smith, Portland, Ore.—Dr. Deaver has referred very derogatorily to the operation of curettage. Nevertheless, I consider this the most valuable conservative operation in the entire domain of gynecology. I do not think that it is ever pardonable to perforate, except rarely in post-puerperal cases, where one should not handle a curette as he would a stiletto. The uterus has been perforated frequently by abortionists, but only rarely by cautious operators accustomed to the use of the curette. Curettage accomplishes more in gynecology, I believe, than all other conservative treatments combined. I will admit that it is bad surgery to curette promiscuously and carelessly in all cases, especially of salpingitis, and that it is not always an easy matter to determine just where these contraindications exist. But if due caution is exercised, curettage is of great value in removing endometric infection, and promoting uterine drainage.

Dr. D. A. K. Steele, Chicago—I can not agree with Dr. Deaver in regard to the abandonment of the vaginal route. I quite agree with Dr. Ricketts as to the many cases in which a vaginal section will evacuate pus, and render unnecessary any further surgical operation. I have had considerable experience with both routes, and had patients die after an abdominal operation who, I believe, would have lived had I used the vaginal route. In many cases of acute infections of the Fallopian tubes, complicated with localized collections of pus in the pelvic connective tissues, adjacent to the tubes, it is the part of wisdom and sound surgical practice to evacuate the pus collection that is extratubal by a vaginal section, and later to laparotomize the patient and extirpate the tube when it can be done with comparative safety.

Dr. Thomas J. Watkins, Chicago—Dr. Deaver has made so many sweeping statements that it is impossible to discuss all of them. The statement about the incision of pelvic abscesses ought not to go by without very severe criticism. Since 1894 I have operated on probably 200 cases of pelvic abscess by vaginal section and drainage, about 5 per cent. of which recurred. If I had operated all of these cases by the abdominal route, the mortality would certainly have been from 10 to 25 per cent. Another thing struck me as being rather odd—namely, that he should encounter so many intestinal complications. In my experience in three hospitals, and in private practice, I almost never have an intestinal complication that requires much attention. It seems to me that in all inflammatory diseases of the uterus, ovaries, and tubes, if we are extremely careful in our manipulations, we can avoid the intestinal complications which have been mentioned. A resection of the bowel after a severe abdominal section for a suppurative disease is certainly of great importance.

Dr. Deaver (closing the discussion)—Dr. Cary said I made a mistake by saying that there are too many lacerated cervices. I repeat that if every woman who has borne children be examined carefully, with an anatomical and not an obstetrical eye, she will be found to have a torn cervix. It is not in the the condition it was before she became pregnant, although it may not have a tear or erosion.

As to Dr. Harris, the strongest argument he presented is that he is not capable of telling which of the two operations to do, and, therefore, his patients are not in safe hands. He speaks of a symptomatic cure. I do not know what that means. I know what a cure means.

Dr. Harris—My symptomatic cure—a cure of pain and symptoms complained of.

Dr. Deaver—As to hematocele, these cases are being operated on to-day, and I have seen them recover. Several of the gentlemen have misunderstood me about lacerated cervix, curettage and dilatation. I did not say that these operations should never be done, but that they are done entirely too frequently by the occasional operator and the family doctor. I stand by that statement. I mean, furthermore, that in the presence of a lacerated cervix and tubal disease, the cervix had better be left unrepaired than repaired. You arrest the drainage from that uterus, and you convert a latent into an active salpingitis. I am sure that every surgeon of experience will agree with me in this.

Dr. Ricketts raised the question as to my experience in obstetrics. For some years I was an obstetrician, but I am one no longer. I confine myself to surgery. I see plenty of cases of puerperal infection, but I see very few cases of so-called pelvic cellulitis with abscess formation. I defy Dr. Ricketts or any other man to thoroughly evacuate pus tubes by vaginal puncture without doing more damage than good. I practice vaginal puncture; I have plenty of patients appear in the hospital with a fluctuating mass in the pelvis, elevated temperature, and without ether I take the knife and slice the roof of the vagina, evacuating a quart or more of pus. I do not call that an operation. My gynecologic friends would certainly call it an operation. I would like these gentlemen to understand that my friend, Dr. Price (who is not here to defend himself), and myself use discrimination in the selection of our cases. We do use vaginal puncture, and we operate through the vagina; therefore, I know that I have been misunderstood by many of the gentlemen present.

Dr. Ricketts refers to lighting the dismal swamp. I know of no light that will be of any aid in that operation. I do not speak of vaginal puncture, but I mean an operation in the sense that you are going to deal with these pus tubes as thoroughly and as effectively as you can from above.

Dr. Smith also attacked me on lacerated cervix. I hope he distinctly understands that I believe that a woman with a badly lacterated cervix, or a second-degree lacterated cervix, if she comes from a carcinomatous family, should certainly be operated on, but I do not believe that a mild degree of laceration of the cervix will, if operated on, prevent a carcinoma. A surgeon with twenty-five years' experience is not going to give up what he has learned from practice for what he is taught by theory. I amputate as many breasts as the majority of surgeons, and 33 per cent. come from a cancerous family. I find in my experience that in the majority of cases of carcinoma of the uterus I see—and I see a fair proportion—I have no trouble in eliciting an hereditary history, either in the mother, grandmother, or great-grandmother. I believe that a lacerated cervix of any degree should be repaired if for no other reason than to prevent the possible likelihood of a cancer. I wrote the latter part of that paper for the purpose of exciting just such a discussion as has been excited.

Dr. Smith talks about office treatment. I wish there was not a doctor in this country to-day who makes an iodin or carbolic acid or tampon treatment in his office. I have seen more disturbances of the pelvis in patients who have been subjected to such treatment. The object of my paper has served its purpose. Of course, I do not expect gynecologists to make these errors, but it is a warning that the gynecologist as well as the surgeon must give to the family physician and the occasional operator, who feels he is capable of discriminating.

Clinical Report.

CIRRHOSIS OF LIVER—REPORT OF A CASE.

C. S. MUSCROFT, M.D.; H. A. INGALLS, M.D.
CINCINNATI, OHIO.

G. H., aged 45, had been a user of wine, beer, and whisky since early manhood, but family history was good, and he never had syphilis. The patient was seen by Dr. Muscroft about April 15, and presented the typical signs of cirrhosis of the liver: jaundice, abdomen greatly distended with fluid, feet and legs edematous, pulse rapid and weak. The liver could not be outlined owing to abdominal distention. Paracentesis was advised, but rejected. The condition was not materially improved by the administration of diuretics, laxatives, regulation of diet, baths, etc. On May 1 the patient was tapped, and 370 ounces of fluid withdrawn. Percussion revealed a very small area of liver dulness. The tapping was followed by an improvement of all his symptoms; medication was continued and the edema of the feet and legs was much reduced.

The improvement was of short duration and in ten days the condition was as bad as when first seen; the toxic symptoms being more pronounced. A urinary examination was made, but no albumin or casts found. On consultation, the toxemia becoming more marked, it was decided to offer the patient the benefit of the Talma-Morison operation, and the patient was removed to the Presbyterian Hospital, where we operated on the morning of May 11. The usual technique was followed: two incisions, a large one above and a small one below the umbilicus, were made, and a drainage tube inserted into the pelvic cavity through the smaller opening. The table was then elevated to gravitate the fluid to the pelvis, so that drainage could take place while other work was being done. The liver was found to be a typical "hob-nail," thus confirming the previous diagnosis. With dry gauze sponges the visceral and parietal peritoneum were irritated and the omentum sutured to the anterior abdominal wall. Continuous drainage was decided upon, so the tube was allowed to remain in the lower opening. The wounds being closed and dressed, the peritoneal surfaces were held in contact by means of adhesive straps across the abdomen.

At the beginning of the operation the pulse was 150 and weak. At the close of the operation pulse was 116 and stronger. Dr. Allan Ramsey, who administered the chloroform, states that but a small amount was necessary. The patient rallied without nausea, and took sixteen ounces of liquid nourishment during the afternoon and night. The symptoms of toxemia became very pronounced during the night and the patient gradually sank in spite of transfusion and stimulants, and died about thirty hours after the operation.

The writer saw this operation performed under cocain anesthesia about three years ago, but the result was the same, death from toxemia. From observation of the two cases mentioned and a study of the literature, the following deductions are made: 1. The prognosis is very bad in those cases of long standing presenting toxic symptoms. 2. Results under both general and local anesthetics are about equal. Theoretically, local anesthesia should be used. 3. Shock is not noticed, these patients being in better condition after than before operation, due, no doubt, to the briefness of the operation and the inhibitory action of the bile. 4. Transfusion should be practiced at the time of operation. 5. Early operation should be advised.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, JULY 6, 1901.

THE PATHOLOGIC EXHIBIT AT ST. PAUL.

No sooner was the Section on Pathology and Bacteriology of the Association formed than it had placed upon it the responsibility of the management of the Pathologic Exhibit. This was entrusted to a special committee, of which Dr. Frank B. Wynn was made Chairman, and in order to defray certain necessary expenses the sum of $500 was set aside for the use of this committee. Hence, the Exhibit at St. Paul was the first official attempt of this kind. Surely no one who visited and inspected the large, conveniently displayed collection of varied and interesting nature, in the Ryan Annex, but will agree that the committee had done its work very successfully and that the money expended was put to good use.

The Exhibit was interesting from various view-points. Perhaps the beautiful preservation of natural colors seen in many of the specimens preserved for museum purposes by Kaiserling's method, or some modification thereof, would attract the special attention of the more hurried and superficial inspector. But even the expert pathological anatomist could not but admire the perfect result demonstrated by some of the exhibitors. And the general practitioner had here a splendid opportunity to see the gross lesions of many of the diseases, rare and otherwise, which he sees more or less frequently clinically. The instructiveness and suggestiveness of the pathological specimens were surely of much value to many. A series of bacterial cultures, mounted in a novel manner, attracted considerable notice because of their value for demonstration and instruction.

In the second place there was a large number of exhibits illustrative of original work in anatomy, normal and pathologic, and in bacteriology, consisting of gross and microscopic specimens and photographs. Perhaps the exhibits of this character were not so immediately attractive as the more showy and more purely museum preparations already referred to; but the significance and value of the specimens illustrative of scientific work grew apace on closer study. The specimens constituted the public documentation of work already published or in the course of publication; many were accompanied with full written or printed explanations and drawings. Among the more striking exhibits of this character mention may be made of a series of successful transplantations of sarcoma in white rats, showing the growths in various parts of the animal, and the collection of photographs illustrative of the various aspects of blastomycetic dermatitis, clinical, histologic, and mycologic. Some of the papers read before the Pathologic Section were illustrated by means of demonstrations of specimens of this kind.

In the third place, a beginning was made in illustrating methods of teaching by the exhibition of a number of student note-books and drawings from laboratory courses—an excellent idea that ought to lead to larger exhibits of this or allied nature in the future. There were also a number of miscellaneous exhibits of historic and other interest. It is quite evident that the term "Pathologic Exhibit" hardly expresses the scope and varied nature of the material brought together. Scientific Exhibit would be better. As expected, the institutions in the region naturally tributary to the meeting place furnished the larger bulk of the exhibit. Some specimens were brought from considerable distances, however.

As to suggestions for the future, the most important because of such general character, would be that efforts should be continued to extend the scientific tendencies noted in the St. Paul Exhibit. Material illustrating original work, demonstrations of special technical methods, of methods and results of teaching and practical demonstrations of various kinds should be secured. Anatomical specimens of all kinds, always welcome, may well begin to share the attention with exhibits of a physiological and chemical character. Probably the fusion of the Section on Physiology and Dietetics with that of Pathology and Bacteriology will lead to a better representation of scientific physiology, not only in the exhibit, but also in the Association at large. The St. Paul Exhibit was gratifying also because of the absence of all commercial taint on the part of the exhibitors and because there was no evidence of the presence of morbid curiosity seekers.

MEDICAL ORGANIZATION.

It seems from an editorial in the *Lancet*,[1] that the members of the medical profession of Great Britain, in their attempt at organization, have the same arguments to meet that we have in this country. One of these, and the most often used, sometimes by physicians themselves, is that we are forming trade-unions. The *Lancet* very correctly states that while we do not decry trade-unions, there is a decided difference between such and the organization of medical men which is being so slowly accomplished. There is no denying that trade-unions have sometimes been animated by nobler sentiments than the desire to extract from the employer of labor the maximum of pay for a minimum of work. If the tyranny of capital has been replaced by the tyranny of labor, the situation is one that usually adjusts itself. But admitting this, professional union means something more than this; we can not rid ourselves of our higher ideals, and the very existence of a system of medical ethics as a living force in the profession gives the lie to those who would compare medical organization to trade unionism. The fact that this is done by English politicians and lawyers like Chamberlain and Grimthorpe, shows either their utter lack of principle or how superficially they have regarded the subject.

---

[1] June 15.

The ideal organization of the profession is along ethical lines and no other is intended. It is daily becoming more plain that it is only by some combination and organized effort that the true ethical spirit of the profession can be preserved and that violation and perversion of its mission by individuals and cliques can be avoided. Especially is it needed to prevent our exploitation by other organizations whose methods and aims are the reverse of ethical in any sense of the word. We can not keep up our elevated standards by subordinating ourselves and them to outside selfish interests. The need of some movement in this direction is not less in this country than in Great Britain, though each country may have its special problems to meet.

That our British confrères are awake to the situation is shown by the editorial referred to, and also by other evidences. One of these is given in a letter published in the *British Medical Journal* of the same date, referring to the reorganization of the British Medical Association:

"Five pounds a year and consent to the discipline of combination would not be too much to give, if through the British Medical Association the medical profession could become organized, self-protecting, and consequently self-respecting and respectable. In these days of organization in all callings, the only one not doing so will naturally go to the wall, and its position become intolerable. One thing is certain, that conservatives, liberals, radicals, anti-Boers, pro-Boers, millionaires, and workingmen, Chamberlains and Steads, are all quite agreed on one point, namely, to exploit the medical profession to the utmost of their power, and on submission, laugh in their sleeves when referring to 'the noble profession,' 'the patriotism of the profession,' a profession which for the most part receives a beggarly pittance, considering the time, energy, and money spent in obtaining a degree or diploma; not to say that it is without honor in our own country, which has been practically shown twice over lately, when ministers of the government have held us up to derision in the House of Commons. The position, bad as it is, will get worse so long as we remain 'an unorganized mob.' We must follow the general example; combine professionally, and take a more active share in politics."

If the American profession, as well as that in Great Britain, is to become duly respected it must protect itself; it must become "organized, self-protecting, and consequently self-respecting and respectable."

TREATMENT OF GONORRHEA WITH NITRIC ACID.

In the presence of disease the object of treatment is the repression of the morbid process and the prevention of complications and sequelæ. There are few specifics, the indications for therapeutic measures being in most instances either physiologic or empiric. Notwithstanding the many remedies recommended at different times in the treatment of gonorrhea, silver nitrate still remains one of the best, if not the best, for this purpose. Its use, however, is attended with the disadvantage of being followed by unpleasant burning of such a degree that many patients are fearful of its employment. Inasmuch as argentic albuminate and proteid combinations of nitric acid result from the application, Popper[1] was led to make urethral injections of a solution of nitric acid in order to avoid the generation of heat caused by the chemic decomposition of silver nitrate. Cocain or eucain may be added to the solution for anesthetic purposes. In cases of acute gonorrheal urethritis a 10 or 15 per cent. solution of pure concentrated nitric acid was injected from three to five times daily, the fluid being permitted to remain in the urethra for one or two minutes. In the course of from twenty-four to forty-eight hours the character of the copious discharge will have changed. The urine becomes clear and contains only fibers. The secretion is viscid and considerably diminished. In the course of five or six days at times only a small drop can be expressed; later only in the morning. In the course of a week in most instances the discharge is even still less. The gonococci also rapidly diminish in number in the course of a day and disappear wholly in from five to eight days. The mucous discharge contains many epithelial cells, which are in part filled with gonococci. For three or four days after the gonococci have no longer been demonstrable the injections are made but twice a day and then but once a day. After from twelve to fourteen days astringents are prescribed for the purpose of causing the disappearance of any filaments that may yet be present. If the discharge is not increased following a seminal emission, or gonococci do not appear, the injections are gradually discontinued, so that the treatment shall be concluded in from fifteen to thirty days. In chronic cases or in the presence of posterior urethritis, a 25 per cent. solution of nitric acid is injected once daily by means of Guyon's syringe. At times the strength of the solution is increased and the injections are made less frequently.

The opinion is expressed that the good effects resulting from the employment of silver nitrate and copper sulphate in the treatment of gonorrheal urethritis are attributable to their coagulating action, while the newer combinations of casein, albumin and peptone with silver, which are precipitated when injected into the urethra, exert only a mechanical influence like pure water, solutions of boric acid and physiologic salt solution. It is believed further that nitric acid is not the only agent capable of yielding the admirable results described, but that other coagulating substances, such as chromic acid and picric acid, have a like action, the acid reaction of the solution also possibly contributing to the bactericidal effect.

---

[1] Centralbl. für die Krankheiten der Harn- und Sexual-Organe, B. xii, H. 4, p. 184.

In explanation of the results obtained it is suggested that the epithelial cells injured by the toxins generated are attacked by the nitric acid and their desquamation thereby favored. The method described has been on trial for two years, and experience has shown it to be more rapid and milder in action than the use of silver nitrate. If in the course of treatment the discharge does not become thin and serous, if the mucous membrane becomes sensitive and erections painful, the treatment is continued by means of astringents. Often the urine becomes entirely clear. Sometimes, however, filaments that contain no gonococci persist for several weeks or months.

TUBERCULIN.

The furor excited among physicians and laity, in 1890, by the announcement that Koch, the discoverer of the tubercle bacillus, had also discovered in tuberculin a cure for tuberculosis, will not soon be forgotten. The disappointment, not to say disgust, that followed when Virchow and others proclaimed the dangers attending the use of the new remedy, will likewise long be remembered. Physicians and laity feared to employ the remedy and it was generally discarded. A very few used it cautiously for purposes of diagnosis. A still smaller number, including several Americans, employed it as a curative agent. Among these was Goetsch, of Slawentzitz, who now, at the end of ten years, and at the solicitation of Koch, publishes his statistics.[1] He tells us in plain and simple language, having the ring of honesty and the marks of scientific accuracy, that from 1890 to 1900 he has treated 175 cases of tuberculosis with Koch's tuberculin with a percentage of cure of 71, that is, 125 have been cured and 50 improved. The record is startling, even when we consider that his cases are carefully selected ones, where the process is not far advanced, and where mixed infection has presumably not occurred.

Goetsch makes his diagnoses by the history and physical signs, but has called no case tuberculous unless tubercle bacilli have been found, or unless there is an unmistakable reaction to tuberculin; and he calls no case cured unless bacilli disappear and the patient tolerates without reaction a large dose, even up to one gram, of the old tuberculin.

He lays down three rules that should be followed: 1. The treatment should only be begun when the patient is free from fever. 2. The dose should not be increased until the last dose is tolerated without reaction. 3. The patient, on the day of the injection, as well as on the day following, must remain in bed.

His illustrative cases seem convincing, and those who have all along hoped that in tuberculin there was an agent that, rightly employed, might rank with quinin and diphtheria antitoxin as a specific, will again take courage from this contribution to the subject, and will await eagerly for confirmation from other quarters of the remarkable results reported by Goetsch. For, as said before, even granting that he selects only the favorable cases, the incipient ones, the results seem marvelous and, if supported by other investigators, will go far toward restoring to favor the despised tuberculin.

MEDICAL EDUCATION AND ITS RECOGNITION BY THE RICH.

It is satisfactory to see things coming our way at last. The recent donation of a million dollars to Harvard University, the Carnegie fund for the Scottish schools, the Rockefeller fund for medical research, and still other donations and endowments for medical instruction, indicate that the branch of scientific education which pertains to prevention and cure of disease is at last being considered. It is to be hoped that this is only the beginning of better things and that the endowment of medical research and medical education will soon be the rule and not the very rare exception, as has been the case heretofore.

THE ILLINOIS MEDICAL PRACTICE ACT.

The Illinois Supreme Court, by what seems a rather technical decision, has interpreted the Illinois medical practice act in such a way that it is impossible to discipline for unprofessional conduct any one whose certificate antedates the passage of the present law in 1899. It was certainly not the intention of those who framed the law to have this interpretation put upon it, but in the redundancy of their legal phraseology they make it open to this construction, which the court adopts. The result is that any one licensed before July 1, 1899, is free to practice any kind of quackery without any recourse on the part of the state. Only licensees under the law now in force can be disciplined. The court, according to the press reports of the decision, makes the suggestion that the defect in the law can be corrected by legislation, which it is hoped is the case. It is also to be hoped that the amendment can be so drawn up as to carry out the intentions of the makers beyond all possibility of any annulment by court decision.

AN EXAMPLE OF THE EDDY LITERATURE.

As an example of how words can be thrown together in such a manner as to sound sweet and beautiful, and at the same time mean nothing, Mrs. Eddy's "Key to the Scriptures" is a magnificent example. What is needed by the ordinary mortal is a key to the "Key," to unlock the mysterious secrets covered up by the verbiage in that money-making and awe-inspiring book. On a small scale, however, Mrs. Eddy's recently delivered speech, which we have no doubt is appreciated and understood by her followers, is another charming illustration of what she can do with words when she tries. The newspapers announce that at the recent gathering of her pilgrims Mrs. Eddy appeared on the balcony and said: "Beloved brethren"—nearly all present were women—"My joy in meeting with you, is my present text. When we shall meet again, will be my next. I think you will agree with me that you have heard sufficiently from me in my message. I will only look upon your faces and then return again to my studio." We would advise those interested to take this "speech" to some shady, secluded spot, beside a cool and babbling brook and study and ponder over it. Its secret meaning shall be revealed. There is a hidden meaning, although the non-adepts may not be able to discover it, especially just what is hidden in the first two sentences.

SYPHILITIC FEVER.

The fact that physicians do not seem to be sufficiently alive to the general fact that syphilis may be the cause of obscure forms of fever, which yield only to proper antisyphilitic treatment, leads Futcher[1] to report three interesting cases of this kind. The most obscure cases of this category are those in which there are no evident outward manifestations of syphilis. Futcher points out that fever in syphilis sometimes, though rarely, occurs so long as three or four weeks before the appearance of the eruption; it may occur just previously to or coincident with the secondary eruption, constituting then the so-called "fever of invasion"; and the fever may come on at any time during the secondary or tertiary stages. In one of Futcher's cases it appeared twenty-nine years after the initial lesion. Syphilitic fever may be continuous and mild, of a remittent type, and of a definite intermittent type, being often mistaken for malaria, typhoid, sepsis, etc. Janeway has cited a number of cases of syphilitic fever which had been diagnosed and treated as tuberculosis, some of the patients having been sent to sanatoria for the tuberculous, and yet the fever and other symptoms promptly disappeared with specific treatment. Enough has been said to emphasize that all cases of fever of obscure origin should be studied with syphilis in view. Evidences of tertiary lues should be sought for in such obscure fevers the exact cause of which is absolutely unknown.

A DECAYING RACE.

According to the Honolulu *Commercial Advertiser,* the Hawaiian race is progressing rapidly toward extinction. This is not strictly news, for it has been long well known to be the fact, but it appears that there has been a decided acceleration of the process within the past two or three years, and matters are more likely to be worse than better. The causes hitherto effective, the neglect of infants by native mothers, the gradual diminution of the *poi* and fish supply, and the spread of loathsome disease, have been reinforced by the newly-acquired vice of opium-smoking. The increasing cheapness of the drug has placed it within the reach of even the poorer Hawaiians and they have the natural disposition to indulge in it. They lack, however, the racial vitality and self-control of the Asiatic consumers, and the results are, therefore, the more disastrous. Their natural improvidence and carelessness of the future is also against them; they see the precipice ahead, but the desire for the present indulgence is imperative and they do not care. The paper quoted says that there are probably now living men of voting age who will see the last full-blooded Hawaiian native, "but that long before that the race will have become a negligible quantity." There is something tragic in the utter annihilation of a race, especially one so amiable in many respects as are the Hawaiians, and it is to be hoped that something may be done even yet to check the tendencies that are causing their decay.

THE UNSENTIMENTAL NURSE.

The trained nurse is a much belauded personage, especially in her graduation addresses, but she also comes in for her share of criticism. Dr. Malcolm Morris and others find her often conceited and too unconscious of the due subordination she owes to the medical profession, of which she is a sort of useful parasite. Others have criticised also, but in a recent issue of a lay journal we find even her merits, from a physician's point of view, are taken exception to by those who endure her ministrations. It objects to her noiseless efficiency, her conscientious regularity, her simulated amiability, her mechanical perfection in the performance of duties; her emotional impassibility, it says, spoils all the pleasures of illness; the patient can make no appeal to her sympathy and she only aggravates his irritability. What the average inexperienced male "who wants to enjoy the pleasures of illness," desires, the newspaper says, "is a ministering angel with actual human sympathies, whose feelings will be touched by human suffering, whose gentle hand will smooth the pillow and cool the fevered brow, and all that sort of sentimental thing," not a self-contained and unimpressionable female, as methodic as a machine and "as dead to his personality as a wooden Indian." Personally, we do not know what the pleasure of illness is, something, we suppose, like the dying of a rose in aromatic pain, etc., but we can appreciate the nurse's position when in unavoidable attendance upon a patient of that type, so far as our fancy can reproduce him. It may be that some nurses are wooden in their ways and obtrusive in their lack of sympathy. If so, it is an error, but one that is on the whole less likely to do mischief than the opposite extreme. To be a philanthropist, as Dr. Sevier says, one must be cold-hearted, and most certainly an inflammable-hearted female philanthropist in a hospital, or even in a sick room, is a dangerous thing. When a nurse can, with all her other requirements met, steer clear of the Scylla of emotionalism on the one hand and the Charybdis of indifference on the other, she is a wonderful creature, common as she may be, and then if she is still criticised one ought to love her for the enemies she has made.

LANDRY'S PARALYSIS OF DESCENDING TYPE.

Although the nature of so-called acute ascending paralysis is not definitely known, there is ground for believing that the condition is dependent on some morbid process, probably infectious-toxic, expending its influence upon the lower motor neuron, that is, upon the ganglion-cells of the anterior horn of the spinal cord or the peripheral motor nerves or both. That no lesions are demonstrable would seem to indicate that the action is essentially a toxic one short of inflammation or degeneration. As a rule the symptoms of the disorder are of ascending character, paralysis appearing first in the lower extremities, then in the trunk and finally in the upper extremities. So common is this mode of invasion that it has come to be considered distinctive. That this is not so would seem to be shown by a case reported by Leonard A. Rowden.[1] The patient was 10 years old, and fell a distance of ten feet into an excavation, without apparent bad results. On the following day he did not feel well and held his head as if he had a slightly stiff neck, and he vomited once after taking some light food. During the night he was rather restless, and on the following day he complained of slight headache and pain in the neck. The succeeding night he was again restless and there appeared to be slight fever. A day later the temperature was found to be almost 103, the pulse 100 and good and respiration normal. The head could not be voluntarily turned to either side, but there was no difficulty in passive movement. There was also inability to raise either arm at the shoulder-joint. The grasp of each hand was fair, the forearms could be readily flexed and extended at the elbow-joint and the legs could be kicked about briskly. On the next day there was complete paralysis of the muscles of both upper extremities and of the trunk and also of the intercostal muscles, with total paralysis of the lower extremities. There was no headache, no rigidity, nor twitching of the muscles, no loss of sensibility, and the mental powers were preserved, as was also control of the sphincters. In the further progress of the case the paralysis of the legs became more advanced and the muscles of deglutition seemed somewhat involved. The knee-jerks were lost, and the facial muscles were later involved and speech became indistinct. The pulse grew rapid and weak, the heart failed, cyanosis developed and death ensued after an interval of five days. Unfortunately, an autopsy could not be secured, but the symptoms and the course are sufficiently distinctive to justify a diagnosis of Landry's paralysis of descending type.

---

[1] New York Medical Journal, June 22, 1901, The Journal A. M. A., page 63.

MISUSE OF THE NATION'S NAME.

The New York State authorities have issued a certificate of incorporation to a concern styling itself "The United States Board of Health," whose business is announced to be the issue of certificates setting forth the purity or harmlessness of food products and patent medicines. Its name is claimed to have been copyrighted by the trick of printing a report bearing same. The official who issued the copyright is said to have "raised a question," as well he might, as to the name; but he issued it nevertheless. Of course the undisguised intention is to sell, to all those who will pay for them, certificates which to all appearance come from a government board of health, guaranteeing their products as having been analyzed and found fit for food by United States officials. The authorization of such a corporation, under such a name, is an outrage upon the people of the entire nation, compared with which the "use of the flag for advertising purposes" sinks to nothingness. There was a time when the coupling of the name of the United States, or some particular state or city, with a private enterprise was regarded as simply a token of patriotism or of state or local pride. "United States" or "New York" or "Minnesota" banks, insurance companies or hotels, were, in this view, quite unobjectionable. But latterly a class of unscrupulous adventurers in various lines of business have taken to using such names for purposes of deception and fraud; and they find numerous victims among the less informed members of the community. Evidently the time has come when some department of the Government should be clothed by Congress with the power to prohibit the use of the name "United States" for any purpose of fraud or deception.

The above is from the St. Paul *Pioneer-Press* of June 18. With the facts as above given the matter is one that interests the medical profession and might well be considered by the Committee on National Legislation of the American Medical Association. If Armstrong or Buchanan should ask for a certificate of incorporation for the United States Government Medical College, they could probably obtain it under the laws of some of the states. For our credit abroad, as well as for our welfare at home, we should most decidedly abridge this liberty.

Medical News.

ILLINOIS.

St. Francis Hospital, Evanston, was formally opened, June 29. The hospital has accommodation for 20 patients.

Dr. Arvid E. Kohler, Moline, has been elected physician for the poor of that city.

Sterling physicians recently held a meeting at the office of Dr. Frank Anthony and adjusted and revised the fee-table.

Drs. Louis H. Clampit and William C. Cole, Jacksonville, have been appointed to the medical staff of the Illinois Central Hospital for the Insane at that place.

New Hospital at Quincy.—The trustees of the Illinois Soldiers' and Sailors' Home at Quincy have approved plans for a new hospital for the institution. An appropriation of $24,000 was made by the state legislature for this purpose. The hospital will accommodate 90 patients.

Chicago.

Jenner Medical College held its commencement exercises, June 20.

Dr. and Mrs. James M. Fraser sailed for Liverpool, June 11, on the *Servia*.

Dr. John A. Robison has resigned as professor of medicine in Rush Medical College.

Dr. C. Pruyn Stringfield has been appointed a colonel on the staff of Governor Yates.

Dr. E. J. Senn has been appointed assistant professor of surgery in Rush Medical College.

Dr. Ernest A. Matthaei and Dr. Paul R. Welcker and wife sailed June 8 on the *Patricia* for Hamburg.

Prof. Nicholas Senn was given the degree of Master of Surgery by the University of Chicago, June 21.

Prof. L. Hektoen left last week for a three months' holiday in Sweden. He will devote all his time to recreation and pleasure.

Dr. John M. Dodson was elected president of the Alumni Association of the University of Wisconsin, at the annual meeting, June 19.

Dowieites Appeal Denied.—Judge Clifford has dismissed the appeal of Henrika Bratsch, a deaconess in the Zion church, who was fined $100 by Justice Everett for practicing medicine without a license.

Globe-Circlers.—Drs. Nicholas Senn, Jacob Frank and Daniel R. Brower and W. M. Maston, of Mobile, Ala., have sailed for Europe. They are to make an eastward trip around the world via Berlin, Moscow, Siberia, Vladivostock, Corea, Japan and Vancouver, reaching Chicago about October 1.

St. Mary's Hospital.—The cornerstone of the Hospital of St. Mary's, which is to occupy an entire block, bounded by Haddon and North Hoyne avenues and North Leavitt and

---

[1] British Med. Jour., May 4, 1901, p. 1076.

Thomas streets, was laid with appropriate ceremonies, June 16. The foundations have been laid and the building will cost about $200,000.

Wesley Hospital, at Dearborn and Twenty-fifth streets, was informally opened, June 17. The formal dedication is deferred until $25,000. the balance of the $250,000 required for the purchase of land and the erection of the building, has been raised. The building is six stories in height and contains 250 rooms.

St. Francis Hospital, Evanston, has been established by the Sisters of St. Francis in the Kirk mansion on Ridge avenue. Its staff is as follows: Dr. John B. Murphy, consulting surgeon; Drs. William A. Kimmit and William Hessert, surgeons; Drs. Edward H. Webster, William A. Phillips, William B. Parkes, Evanston, and George Sintzel, Niles Center, physicians; and Dr. Shobal V. Clevenger, nervous and mental diseases.

Fire at the College of Physicians and Surgeons.—A fire, started by lightning, damaged the College of Physicians and Surgeons to the extent of at least $40,000, June 25. As the West Side Hospital, which adjoins the college building, appeared to be in danger, the 69 patients were removed to the County and Presbyterian hospitals, where they were cared for. The removal was accomplished without any casualty, thanks to the discipline and coolness of the nurses of the hospital. The two upper floors of the college building sustained the most damage. The library, many microscopes and the fine pathological exhibit made by Dr. W. T. Eckley at the meeting of the ASSOCIATION in St. Paul, were destroyed beyond repair. The building was fully insured. It will be repaired and equipped for the use of the dental department of the University of Illinois; the medical school will remove to the recently acquired West Division High School property, which is now being remodeled for that purpose.

KANSAS.

Dr. Henry O'Donnell, Ellsworth, has been appointed surgeon-general of the Kansas National Guard.

A hospital for colored people will soon be erected in Leavenworth. Much of the money needed has been subscribed.

The State Board of Medical Registration and Examination completed its organization, May 21, and elected Dr. George F. Johnson, Lakin, president, and Dr. W. H. Roby, Topeka, secretary.

Registration.—Under the new law, Kansas physicians will have till September 1 to file with the secretary of the examining board their authority to practice. If the authority is sufficient, the board will issue certificates. After September it will be an offense to practice medicine without a certificate from the state board. The penalty is a fine of from $1 to $200. The examination fee is fixed at $15. The fee for certificates to physicians who do not take the examination is $2.

KENTUCKY.

A new hospital is to be erected in Louisville at a cost of $50,000 by the Franciscan Sisters.

Quarantine Against Carlisle.—The health officers of Bath County on May 30 proclaimed the establishment of an absolute quarantine against Carlisle on account of the prevalence of smallpox in that town.

Smallpox at Cynthiana.—Dr. N. W. Moore, health officer of Cynthiana, has sent the following report of the smallpox condition at Cynthiana, on May 21. Since April 6 there have been 54 cases and no deaths. Two large pest-houses—one for whites and one for colored, have been erected and contained 6 cases at the time of the report. There were then only 4 cases in the immediate town, and several cases were distributed through the county.

LOUISIANA.

Dr. Guy A. Darcantel, New Orleans, has been appointed by the State Board of Health, resident physician at Rio Cocle, Colombia, Central America.

Dr. A. B. Brown, New Orleans, has been appointed one of the physicians of the United Fruit Company and has been assigned to the steamer *Jamaica.*

Dr. Arthur Weber, newly appointed member of the New Orleans Board of Health, has had his claim to membership confirmed by Judge John St. Paul, who has issued a peremptory mandamus compelling the board to accept Dr. Weber.

New Quarantine Station.—The proposed establishment of a quarantine station by the State Board of Health at Lake Borgne Canal as soon as it is opened to traffic, is meeting with general approval. There will be need of a health station at that point on account of its direct communication with Mississippi sound.

MARYLAND.

New Course at Johns Hopkins.—During October a limited number of physicians will be admitted to a special class for the study of the important tropical diseases met with in this region, especial attention being given to malaria, dysentery and typhoid fever. Preference will be given to officers of the medical departments of the army and navy.

The Maryland Medical Journal Company, at its annual meeting in Baltimore, June 13, elected Dr. Robert T. Wilson, vice-president, Dr. Horace M. Simmons, secretary and general manager; Drs. William Osler, William H. Welch, John D. Blake, Wilmer Brinton, Hiram Woods, Jr., and Julius H. Wyman, directors; Dr. John S. Fulton, editor, and Dr. Thomas R. Brown, associate editor.

Preventive Treatment of Rabies.—The Department for the Preventive Treatment of Rabies (Pasteur method) at the City Hospital, Baltimore, has published a detailed report of the 209 cases treated. But one death is reported, and this is considered to have been due to delay in resorting to treatment. Of the 209 patients 15 were bitten on the face and neck by animals proven by inoculation to be rabid. Some of these bites were very severe, but none resulted fatally.

Baltimore.

Kerosene for Mosquitoes.—Health Commissioner Bosley has issued a proclamation to the people, asking their co-operation in the extermination of the mosquito. He advises every householder to pour one gill of kerosene oil into all wells and a proportionate quantity into all pools and drains where stagnant water may collect at least once every two weeks.

MICHIGAN.

Dr. Herbert M. King, Grand Rapids, sailed for England, July 2.

Dr. Conrad Georg, Jr., has been appointed city physician of Ann Arbor.

The Medical Department of the University of Michigan graduated a class of 75, on June 20.

Mr. Frederick Stearns, of Detroit, eminent as a conchologist and pharmacist, and formerly president of the American Pharmaceutical Association, has been given the degree of Master of Arts by the University of Michigan.

MINNESOTA.

The State Board of Medical Examiners issued license to practice to 33 applicants, June 15.

A hospital in connection with the State School for the Feeble-Minded at Faribault is to be constructed, to cost about $11,000.

Hamline University Medical Department held its annual commencement exercises at Minneapolis, June 3, graduating a class of twenty-four. Rev. Marion D. Shutter delivered the address to the class on "Progress and Problems of Medicine."

MISSOURI.

Dr. Frank J. Lutz, St. Louis, has been appointed surgeon-general of Missouri, with the rank of brigadier general.

Dr. William H. Heidorn, Bridgeton, has been appointed a member of the pension examining board vice Dr. Samuel J. Will, Mehlville, resigned.

A hospital is to be built on the grounds of the Confederate Home of Missouri, Higginsville, for the use of inmates of that institution. The legislature has appropriated $15,000 for this purpose, $12,000 of which is to be devoted to the expense of construction and the balance to equipping the hospital.

NEW YORK.

Dr. William Carr, New York City, will sail for Europe July 6.

Dr. F. J. Wagner has been appointed house physician at Riverside Hospital, Buffalo.

New Laboratory.—A new laboratory will be built for and adjoining the New York Medical College and Hospital for Women.

Dr. Frank L. Christian, New York City, has been appointed medical superintendent of the Elmira Reformatory. The salary is $3500 with a residence.

Dr. D. Bryson Delavan has been appointed consulting surgeon, department of laryngology, St. Luke's Hospital, in place of Dr. George M. Lefferts, resigned.

Dr. Paul F. Munde, New York City, who has been for many years professor of gynecology at Dartmouth Medical College, has resigned and has been elected professor emeritus of gynecology.

Smallpox on the Increase.—According to the report of the New York City Board of Health smallpox is on the increase in that city. Twenty-two new cases and one death were reported June 12.

Dr. Theodore Walser, New Brighton, who has rendered such efficient service to Staten Island in the prevention and limitation of epidemic disease, has been appointed sanitary superintendent of the Borough of Richmond.

The Lewis Memorial Cottage Hospital, at New Dorp, Borough of Richmond, given to St. John's Guild, was recently dedicated. The building is of wood, 103 feet long and 34 feet, 10 inches wide. It is intended for the reception of infants that are seriously ill, and the two wards will each accommodate eight infants. The cost of building and equipping the hospital was $10,000.

OHIO.

Dr. Alexander Erwin, Mansfield, has returned from a six months' tour of Egypt and Europe.

A so-called magnetic healer was arrested for illegal practice at Rockford, Mercer County, June 19, and was held to the grand jury in the sum of $500. A man charged with practicing medicine illegally was arrested at Findlay, June 15.

The State Board of Medical Registration and Examination examined thirty-nine candidates for license at Columbus, the regular examination on June 11, 12 and 13. The result of the examination will be made known after the regular meeting of the board in July.

College Changes.—Dr. J. C. Oliver has been made dean of Miami College in place of Dr. N. P. Dandridge, resigned, and Dr. Frank W. Langdon has been elected professor of neurology. Dr. D. I. Wolfstein has been made professor of neurology and Dr. Mark A. Brown, professor of clinical medicine in Cincinnati Medical College. Dr. H. J. Whitacre has been made professor of pathology; Dr. William Muhlberg, professor of physiology and Dr. Fred Forchheimer, professor of practice of medicine, taking the chair of the late Dr. J. T. Whittaker, in Ohio Medical College.

Memorial Volume on the Late Dr. James T. Whittaker.—At the meeting of the Academy of Medicine on June 25, 1900, resolutions of regret at the death of Dr. James T. Whittaker were adopted and ordered printed, together with a memorial volume setting forth the principal events in the life of the distinguished physician. This volume has just been distributed among the members of the Academy. It contains a biographical sketch by Dr. A. G. Drury, editor; also reminescent sketches by Drs. P. S. Connor, Thad A. Reamy, J. L. Cleveland, Joseph Ransohoft, C. D. Palmer, S. C. Ayres, A. Ravogli, S. P. Kramer, John Withrow, C. P. Judkins, T. C. Minor, J. C. McMechan, Koehler, Howard A. Kelly, of Baltimore, and others.

SOUTH CAROLINA.

The Medical College of the State of South Carolina, Charleston, held its seventy-second annual commencement exercises, April 2. A class of thirty-two was graduated, the address to the class being made by Major J. C. Hemphill.

Discrimination in favor of the graduates of the Charleston Medical College, as shown in the bill recently passed by the legislature, which exempts from examination graduates of that college, is strongly condemned by the representative profession of the state, which has been successful in checking the ratification of the bill.

The State Board of Medical Examiners, at its May session, examined 46 applicants, 11 of whom failed to pass. The board unanimously adopted the following resolution: "As the law relating to the practice of medicine in South Carolina is being frequently violated, therefore, be it resolved, that we appeal to the legally licensed physicians of the state and to its intelligent citizens to report all said violations to the board."

TENNESSEE.

Dr. Richard Douglas, Nashville, has resigned from the faculty of Vanderbilt University Medical Department.

Dr. James A. Delaney, Bristol, has been appointed division surgeon on the staff of the commander of the Tennessee Division, Sons of Confederate Veterans.

Memphis Hospital Medical College held its commencement exercises April 26, graduating a class of 190. Prof. J. L. Minor delivered the doctorate address.

Grant University Medical College.—The contract for the construction of the new medical college was let June 12, for $22,622.05. The building is to be completed, April 1, 1902.

The legislature has passed the bill creating a State Board of Medical Examiners and requiring the registration of all physicians. The osteopaths and "Christian Scientists" are exempted from the provisions of the act supposedly because they are not physicians.

TEXAS.

Dallas Medical College, which was recently made the medical department of Trinity University, graduated a class of eight at its exercises, June 18.

The Medical Department of the University of Texas held its eleventh annual commencement exercises at Galveston, June 15, graduating a class of six.

The State Medical Association of Texas has been incorporated with principal office at Austin, and without capital stock, by Drs. Berthold E. Hadra, Taylor Hudson, Robert F. Miller, Henry P. Cooke and Hamilton A. West.

Quarantine in Grayson County.—Acting on authority of the commissioners' court and with the approval of State Health Officer Blunt, County Physician Thomas S. Freeman, of Sherman, declared a quarantine against all houses in which there is smallpox.

WEST VIRGINIA.

Drs. James F. Means and C. Edgar Kahle, Sistersville, have sailed for Germany, where they expect to remain for several months.

Dr. Augustus J. Lyons, Parkersburg, has been elected superintendent of the Second Hospital for the Insane, Spencer, vice Dr. L. V. Guthrie, resigned.

State Board of Health.—Governor White has recently appointed the following gentlemen on the State Board of Health: Drs. D. H. Taylor, Wheeling; D. P. Morgan, Clarksburg; T. F. Lanham, Grafton; S. N. Myers, Martinsburg; J. E. Robins, Claremont; A. G. Staunton, Charleston; A. N. Frame, Parkersburg; W. Varner, Glenville, and A. R. Barbee, Point Pleasant. At the annual session held in Charleston, June 11, Dr. S. A. Myers, Martinsburg, was elected president, and A. R. Barbee, Point Pleasant, secretary. Fifty-four applicants presented themselves for examination. The next session will be held in Huntington, November 11.

GENERAL.

Dr. S. Weir Mitchell, with his wife and daughter, reached San Francisco June 24, after a trip round the world. He has been greatly benefited by the rest and change.

Cuba Has No Yellow Fever.—Yellow fever has been combated with such vigor that not a single death has been reported this year. There has not been a fresh case in Havana for nearly two months; neither are there any cases in other parts of the island.

A Foreign Tribute to the Late Dr. Mergler.—The *Gazette Méd. de Paris* publishes an extended obituary notice of the late Dr. Marie J. Mergler, of Chicago, emphasizing her success in abdominal surgery, and stating that Europe has not yet produced a woman operator of that stamp.

Gift to Harvard.—J. Pierpont Morgan has promised to build three of the five buildings desired by Harvard Medical School. This will involve the expenditure of a million dollars, and the buildings are to be devoted to applied biological research. They are erected as a memorial to the late Julius Spencer Morgan, a native of Massachusetts, and a banker of London, the father of the donor.

Prize Essays on Subjects Connected with Tropical Diseases.—1. A prize of the value of £10 entitled the Sivewright Prize, presented by the Hon. Sir James Sivewright, will be given for the best article on "The Duration of the Latency of Malaria After Primary Infection, as Proved by Tertian or Quartan Periodicity or Demonstration of the Parasite in the Blood." 2. A prize of the value of £10 entitled the Belilios Prize, presented by the Hon. E. R. Belilios, will be given for the best article on "The Spread of Plague from Rat to Rat, and from Rat to Man by the Rat-flea." 3. A prize of the value of £10 entitled the Lady Macgregor Prize, presented by Lady Macgregor, will be given for the best article on "The Best Method of the Administration of Quinin as a Preventive of Malarial Fever." The papers are to be sent to the editors of *The Journal of Tropical Medicine*, 83-89, Great Titchfield Street, London, W., by Dec. 1, 1901. All papers sent in become the property of the *Journal*, and will be published as the editors decide. The competition is open to qualified medical practitioners of all denominations and every nationality. The papers may be written in English, French, German, Italian or Spanish. The names of the prize winners will be announced in January, 1902. The judges are Surgeon-General Roe Hooper, Professor Kenneth MacLeod, and Dr. Patrick Manson.

CANADA.

Outbreak of Smallpox.—Between twenty and thirty cases of smallpox have just been discovered in a small village near Brantford, Ontario. The disease is mild in character and occurs among berry-pickers. Dr. Hodgetts, of Toronto, will have charge of the outbreak.

Appointment.—Dr. W. W. Ford, of McGill College, has been appointed to the new Rockefeller fellowship in the medical faculty of McGill. He will be engaged on some subject connected with the study of preventable diseases, under the direction of Professor J. George Adami. Dr. Ford will spend the coming six months at the Pasteur Institute, Paris.

Toronto General Hospital.—The patients at the Toronto General Hospital on Saturday, June 29, numbered 123 males and 68 females. Admitted during the week: Males, 27; females, 24. Discharged: Males, 38; females, 30. Decrease, 17. Average number of male patients during quarter, 163; female, 78.40. Admission during last quarter: Males, 458; females, 365. Discharged: Males, 444; females, 340.

Resolution re Ontario $2 Assessment.—At the recent meeting of the Ontario Medical Association, a resolution was passed unanimously amid hearty applause, and without a single dissenting voice congratulating the Ontario Medical Council on their determination to make practitioners pay this fee, and approving of its being levied in the future. This action of this important body will strengthen the hands of the Ontario Medical Council and enable it to relegate this bone of contention to oblivion.

New Buildings at McGill.—A graduate of the medical department of McGill University three years ago would hardly recognize the old familiar quarters if he were to return to Montreal to-day. During the past year a complete transformation has been made in the structure. The pathologic department is one of the brightest and best equipped of all the departments in the university, and will become a worthy home for the research work which will be carried on at McGill under the direction of the Rockefeller Institute.

Drinking Decreasing in Ontario.—In 1889 the convictions for drunkenness in Ontario amounted to 4797. In 1899 this had dropped to 1892. a decrease of 2905, or over 60 per cent. In 1889 there was one conviction for drunkenness for every 295 persons, and in 1899 one for every 826. The number of persons to each conviction in the provinces of Canada for the year 1899 is as follows: Ontario, 826; Quebec, 461; Nova Scotia, 448; New Brunswick, 253; Manitoba, 355; British Columbia, 207; Prince Edward Island, 341; the Territories, 180.

Infant Mortality in Montreal.—Ninety-one infants died in Montreal during the week ending Saturday, June 22, and this heavy mortality so early in the summer caused much concern among the members of the Health Committee. For the corresponding week of 1900 the number reached sixty-four and that was considered abnormally high. The principal reasons for this heavy mortality among the infant population of Montreal every summer is given as ignorance on the part of mothers as to how to feed and take care of infants; overcrowding is another cause; want of fresh air is said to be another, and noxious privy pits is set down as another cause. In 1891 Montreal contained 8528 of the privy pits, and now 5201 are in existence. Of one hundred cities in America from which statistics could be secured, Three Rivers, Quebec, has the highest death-rate and Hamilton the lowest. The death-rate in Montreal in 1900 was 24 per thousand. This is equal to New Orleans, at 24.8. The rate of Three Rivers is 36.1; of Hamilton, 12.9.

Manitoba University Prosperous.—Four hundred and seventy-three students wrote this past spring on the examinations of Manitoba University in arts, medicine and law, showing that this, the youngest university in Canada, is forging ahead at a rapid rate. Last January the university opened its new science building, which cost $60,000, where the science faculty now lecture to classes formed of the students of the five affiliated colleges. This university receives a very small grant from the Manitoba government and retains the right to appoint its own professors. Belonging to the university are some 150,000 acres of Manitoba prairie lands, which are now valued at from $750,000 to $1,000,000, and it is from the proceeds of the sales of portions of these lands that funds were secured for the new science building.

Toronto Hospital Notes.—The house surgeons for the coming year were appointed on June 28, for the Toronto General and St. Michael's hospitals. A new feature of these appointments is to be found in the selection of two and possibly three women for the staffs of the two hospitals and one for the Hospital for Sick Children. Dr. Helen MacMurchy has been appointed on the staff of the General, while Dr. Margaret MacCallum has received a similar appointment on the Sick Children's. This would seem to indicate that the women physicians had found a permanent footing in the hospitals of the city of Toronto. The members of the new staff of the General are as follows: From Toronto University—F. A. Cleland, W. H. Cromyn, H. S. Hutchison, A. J. Macdougal and J. H. Trout. From Trinity Medical College—Duncan Anderson, James E. Martin, W. J. Macdonald, E. S. Ryerson, and W. G. Collison. To the staff of St. Michael's have been appointed P. W. O'Brien, R. H. Parent and C. R. Elliott.

Executive Health Officers of Ontario.—The annual meeting of this Association was held at Brantford, Ont., on June 25 and 26, the president, Dr. W. T. Connell, pathologist of Queen's University, in the chair. Smallpox was a theme which received careful attention and school sanitation was also carefully considered. One health officer strongly condemned the kissing habit, while another moved for the appointment of county inspectors. A strong committee was formed, consisting of one member from each county in the province who will endeavor, through local committees, to have by-laws submitted to the people for the establishment of country sanatoria. Prof. J. A. Amyot, of Toronto, contributed an important paper on the "Value of Examinations of Throat Swabs as a Test of Freedom from Diphtheria." Mr. Thomas MacFarlane, chief Dominion Government analyst, contributed a paper on "Moss Purification of Closets." The following were the officers elected: President, Dr. E. E. Kitchen, St. George; vice-president, Mr. Thomas MacFarlane, Ottawa; executive committee. Dr. Pearson, of Brantford, Dr. Hoare, of Walkerville, Dr. D. Dunton, of Paris, Dr. John Herald, of Kingston, and Dr. W. J. Arnatt, of Berlin; secretary, P. H. Bryce, Toronto.

Dominion Registration.—A new suggestion to this scheme of interprovincial registration has been adopted by the Ontario Medical Council. At one of their sessions, Dr. T. G. Roddick, M.P., was present, and delivered an address upon the progress the measure had made in Parliament. The matter was referred to a special committee to report on, and a suggestion brought in by Dr. Britton appealed so strongly to the committee, and subsequently to the whole Council, that it was adopted. This may fairly be set down as the policy of the Ontario Medical Council with regard to this question of Dominion registration. The first 100 or fraction of 100 medical practitioners in each province shall be entitled to one representative. The second 100 or fraction of 100 over 50 per cent. shall be entitled to one representative, and for each subsequent 600 one representative shall be allowed. One representative shall be appointed for each province by the Governor-General in Council. and there shall also be three members elected by such practitioners in Canada as are now recognized by the laws of any province as forming a particular and distinct school of the practice of medicine, and as such are entitled to representation on the Medical Council of the Province. There shall further be one representative for each university having a teaching faculty in medicine or a medical college in affiliation with it.

FOREIGN.

Deaths Abroad.—Among the deaths reported abroad are those of Professor Langenbuch of Berlin, of H. Bauer, privat docent at Giessen, and of Dr. Assmus, the founder of the Samaritan emergency corps at Liepsic.

Smallpox in Paris.—The prophylactic measures taken in Paris against the epidemic of smallpox that has been prevailing there since the Exposition, seem to have little effect, as 1790 cases have occurred since the first of the year, with a mortality of 13 per cent.

The sewage farms around Berlin have had no cases of typhoid or malarial fever during the past year, and only 34 deaths to a population of 40,287. Recent official tests failed to disclose any pathogenic germs in the springs of drinking water or in the outflowing drains.

Plague in India.—The blue book on India, just issued, gives the plague mortality for the five years ended March, 1901, as nearly 600,000. The census shows, for the decade, an increase of less than 6,000,000, instead of the normal 19,000,000. This loss is due to famine and disease.

Professor Panas, of Paris, delivered his last clinical lecture June 17; the hall was crowded with his friends and pupils. Twenty-two years previously on that date he assumed the duties of the newly-created chair of ophthalmology, and to his efforts since is due in great measure the progress of this branch of medicine in France.

Honors to Porro.—May 21 was the twenty-fifth anniversary of the day when Eduardo Porro, of Pavia, performed for the first time the operation that bears his name. Laparotomy was rare in those days and Cesarean section was considered extremely dangerous. Porro was considered a reckless enthusiast and actually threatened with criminal proceedings. His friends and pupils celebrated the anniversary by presenting the master with a gold medal and commemorating the event in other ways.

Medical Chemistry Course at the Institut Pasteur.—A new service has been created at the Pasteur Institute of Paris, called "Service d'analyse et de chimie appliqué à l'hygiène." A course is given which is intended for physicians, pharmacists, and for chemists desiring to familiarize themselves with the manipulations of medical chemistry, analysis of food-stuffs and industrial chemistry where the biological phenomena play a part. The lectures and laboratory work continue during six months, entitling the student to a certificate for the work passed. The course begins in November, 1901, and those desiring to enroll themselves can do so by writing to the Pasteur Institute, Paris.

Germany Lowers the Medical Standard.—The German Bundesrath has officially approved the measure admitting graduates of the technical schools to the medical courses in the universities, in spite of the protests of the profession throughout the country. The *Deutsche Med. Woch.* calls upon physicians to do all in their power to nullify the probable evils of the measure. This, it believes, can best be accomplished by informing the public of the deplorable pecuniary condition of the medical fraternity by addresses at suitable places, articles in the lay press, and especially by a prize pamphlet for wide distribution among parents, like the pamphlet on the evils of quackery, of which 28,000 copies had been distributed up to last October. Medical associations are urged to consider the matter at once. The new measure admits graduates of the Realgymnasien unconditionally, but graduates of the Oberrealschulen have to pass an examination in Latin.

British Congress on Tuberculosis.—This congress will be held at the Queen's Hall, London, from Monday, July 22, to Friday, July 26. There will be four sections: 1, State and Municipal, president, Sir Herbert Maxwell; 2, Medical, including Climatology and Sanatoria, president, Sir Richard Douglas Powell; 3, Pathology, including Bacteriology, president, Prof. G. Sims Woodhead; 4, Veterinary (Tuberculosis in Animals), president, Sir Geo. Brown. The following public addresses will be given to the whole Congress: On Tuesday, by Prof. Koch of Berlin; on Wednesday, by Professor Brouardel of Paris, and on Thursday by Professor McFadyean of the Royal Veterinary College. On the concluding day there will be a final meeting to pass resolutions arising out of the work of the Congress. A number of receptions, excursions, etc., have been planned and a large attendance on the Congress is anticipated. It is possible that on this account the general meetings will be held in St. James Hall, as that is specified in the circular of invitation.

German Congress of Dermatology.—The seventh annual congress of German dermatologists was held at Breslau, the last of May, and was principally devoted to demonstrations and discussions. Neisser exhibited plaster casts of an exanthem resembling in every respect a typical papular syphilid, taken from a pig inoculated with syphilis. Wolff has also had similar success in experimental inoculation. Riehl advocated treating pregnant syphilitics with a local suppository containing 1 gm. of blue ointment, as supplementary to general specific measures. By this means he has succeeded in preventing abortions and syphilitic degeneration in the offspring. Schaeffer reported that the local application of heat to inflammatory cutaneous processes arrested the leucocytosis and transformed the process to a mere serous impregnation and hyperemia. Plato lauded the antiphlogistic action of alcohol compresses. Loewenhardt confirmed the diagnostic value of Roemann's method of testing the functions of the kidneys by the electric conductibility of the urine. Scholz and several others described the remarkable benefits derived from thiosamin in the correction of scar-formation and sclerodermia. The former injects ten parts of thiosamin to twenty parts glycerin and seventy parts water, and exhibited a case of extensive lupus which had threatened deforming contraction of the mouth and nose from the cicatrices until the morbid tendency was arrested by the injections. The sensation of the congress, however, was the presentation of a number of patients cured of lupus at Finsen's "Light Institute." Some were under treatment for an hour a day for a year, in others the cure was more rapid.

PARIS LETTER.

Sanatoria for Consumptives.

The question of sanatoria for consumptives has occupied the attention of the medical public in France to a considerable extent during the last two or three years, and efforts have been made to find the funds necessary to erect a certain number of them. One of the latest constructions of this kind is the sanatorium of Agincourt, which was inaugurated in October last and which has room for 70 inmates. A recent investigation made by the director of the Hauteville sanatorium has shown that there are numerous defects in the organization of this institution. Architecturally the buildings are quite imposing, and perhaps too much stress has been laid on this. The whole of the ground floor has been sacrificed to the hydrotherapic establishment of the medical service, and the storehouse. On the other hand, as not enough room for the patients could be found on the other floors, the attics have been arranged for them. The veranda is not well disposed, being exposed to both wind and rain, but there are several parlors where the patients can congregate, and the dining-room, though perhaps too small, is well aired. Several other defects were noticed, such as the distance at which the kitchen has been placed from the dining-room. The German idea of having a physician as director of the establishment, taking a fatherly interest in the condition of his patients, and being able to watch the nurses and attendants at all times, has not been carried out, and it would certainly be much better to have it done, so that the life at a sanatorium should not resemble too much that in a hospital.

Waldeck-Rousseau's Circular on Antidiphtheric Serum.

It is generally supposed that antidiphtheric serum containing any slight deposit is not so efficacious as the perfectly clear serum, and a certain number of physicians refuse to use any such, as they feel they may cause some harm by doing so. Mr. Waldeck-Rousseau, the Minister of the Interior, has sent a circular to the sanitary inspectors concerning this matter. He remarks that the statistics published by the different inspectors give variable results as to the mortality from diphtheria, and this must be due in part to the treatment followed out. Some physicians are unwilling to use old serum, and lose precious time while waiting for some new. Recent experiments have shown that the properties of serum are still intact after a year, and as for the deposit so often seen, it is in nowise an indication that the serum is worthless. If the injection is made the day the false membranes appear, the death-rate is only 2 per cent., the second day it goes up to 6 per cent., the third day it goes up to 30 per cent., and it is 50 or 60 per cent. the fourth day. Dr. Chantemesse, who is in charge of the hospital for diphtheritic patients, spoke on the same subject at a recent meeting of the Medical Society of the Hospitals. He remarked that physicians had been frightened by the reports of accidents that had taken place as a result of the use of these injections, and he wished to say that there had been a good deal of exaggeration about this. In six years time he had never had occasion to notice any in any infant service he had had. He had noticed that only 5 per cent. had received an injection. From March, 1896, to March, 1901, he received into his service 476 children suffering from diphtheria, and 70 per cent. of them died, which is a mortality of 16.80 per cent.; most of these died the first three days, having been already in a very serious condition. It should be laid down as a rule that one should not wait until a bacteriological examination has been made, but inject all suspicious cases. Dr. Chantemesse's experience has shown him that serum containing a slight deposit was just as active.

Widal's Sero-Diagnosis—New Statistics.

A Danish physician, Dr. Tobiesen, has just published some important statistics on Widal's sero-diagnosis in typhoid fever, founded on 350 cases. There was a positive result in 329 cases with a 1 in 10 solution. Seventeen gave a result with dilutions varying from 1 in 10 to 1 in 25. In two cases there was no result, and in two others with one in five. In thirty cases of death followed by an autopsy, the clinical and bacteriological diagnosis was confirmed by the autopsy. Out of 36 deaths the sero-diagnosis was positive in 35 cases, in the thirty-sixth case it was hardly perceptible with a 1 in 10 solution. As a means of diagnosis this method is excellent, as applied to 289 patients forty hours after admission, it was positive in 215 cases. Dr. Tobiosen examined also a certain number of other patients, 151 in all, and obtained a 1 to 10 reaction in 25 cases and a 1 to 25 in 4 others. Sixty-one healthy subjects gave 8 positive reactions at 1 to 10, and 1 at 1 to 25. It would seem to the author that the sero-diagnosis was only of value in case 1 to 50 dilutions gave a result.

Mercurial Injections.

Dr. Dienpart has just published a work on the treatment of syphilis by injections, in which he analyzes the results of 1062 observations, most of which have been collected in the service of Dr. DuCastel. Seventy-eight injections of calomel were followed by rather indifferent therapeutic results, and gave rise to such complications as pain, inflammatory nodi, but there was neither stomatitis nor diarrhea. One hundred and fifty injections of salicylate of mercury were made according to the formula of Dr. Hallopeau, 14 centigrams being used each time. No serious accidents occurred, but the curative action hardly seemed sufficient. Three hundred and nineteen injections of gray oil were followed by frequent stomatitis, and only cured slight cases, and their use in ordinary practice is rather difficult. Fifteen observations were furnished by Professor Dieulafoy where the solution of biniodid and oil was employed. The results were excellent, especially in visceral syphilis, but a daily visit is found necessary in such cases. The best preparation is the bichlorid serum of Cheron, which only needs to be injected once a week. There is a special tonic action due to the use of the saline solution. The results were most satisfactory.

Pozzi's Speech at Opening of Gynecological Course.

Dr. Pozzi, who has been named professor of gynecology, gave his first lecture at the Broca hospital two weeks ago. He showed in his speeech how difficult it had been to obtain the creation of a professorship of gynecology in Paris, and how he had been working to achieve this during the last seventeen years. It was after a trip to Freiburg in Breisgau, where he visited Professor Hegar's service, that he made out a report which he sent into the faculty, which refused to consider his proposal to deliver lectures. In 1887 he was able to give a supplementary course, and he had always tried to obtain for gynecology a better footing than that which it had at first enjoyed. Specialists were looked upon with some disfavor at first, in France, and the services they could render were but tardily acknowledged. Dr. Pozzi gave a short history of the progress of surgical science, and spoke of the conservative tendencies which were beginning to be felt.

Correspondence.

The Canteen.

HARTFORD, CONN., June 27, 1901.

To the Editor:—I have received some letters from members of the Association who were not present at the St. Paul meeting inquiring if the canteen resolutions passed expressed the judgment of the Association at this meeting. I answer, emphatically, "No." No reliable grouping of facts and conclusions on a question on the good or the bad results from the canteen can be settled from six months' experience or the personal observation of any small number of men, and no question of practical science should ever be forced on the Association in the last hour of its session as if afraid of an open, fair discussion. Beyond this the passage of these resolutions was dangerously revolutionary, indicating the possibility of committing the Association to the indorsement of theories and conclusions which any group of men may formulate and shrewdly wait for an opportunity to have them passed. From the earliest time this Association has refused to sell its influence and prestige for the advancement of any partisan or disputed questions. Almost every year resolutions have been offered indorsing various disputed questions of science and hygiene, some of which were of great interest. These resolutions have always been sent back from the committees to whom they were referred as inexpedient and unwise to be recognized formally by the Association. It is apparent to everyone that it would be suicidal for the Association to take part in controversies on unsettled questions where good men equally competent differ widely as to the facts and their meaning. The Association should always represent the best judgment and convictions of facts that are beyond the range of partisan controversy, and should never be at the mercy of a few men who may force their indorsement of any theory or resolution, particularly by methods that are unusual and in the spirit of dogmatism. All such resolutions point out a source of weakness in the organization, and also indicate a recklessness on the part of partisans who take advantage of this fact. It is very evident that at the next meeting some important changes in the constitution and by-laws should be passed to make it impossible for any faction to commit the Association to the indorsement of views and theories which they wish to formulate. If these canteen resolutions are sustained as the experience of the American Medical Association, the door is open for any supporters of other radical theories or statements which may be offered and pressed to a final vote of acceptance at the right moment by shrewd promoters. I am positive in the assertion that these resolutions utterly fail to represent the conservative judgment of the Association, for the reason that there are medical men as competent to judge, and authorities as reliable, who denounce the canteen and all efforts to reinstate it. In this conflict of theory and opinion the great army of the profession refused to be committed to any one view, but hold themselves open for farther and more conclusive evidence. All scientific sense and good judgment is outraged by immature conclusions and attempts to force opinions and secure their indorsement as final. While the Association as a body is always open to hear the evidence offered by both sides, its final judgment and conclusion to be of any value must be of slow growth and be above all possible suspicion of bias and feeling. If these resolutions do nothing more than awaken the Association to the need of providing against any farther possibility of its prestige and influence being bought and sold to the shrewd manipulator with some motive behind, they will have accomplished a great work.

Outside of the merits of this question, all such resolutions commit the Association to battle grounds of partisanships from which nothing but evil can come. The recognition and acceptance of facts is as inevitable as the growth of the seasons, and no controversy or indorsement is needed, and the canteen or anti-canteen will be decided higher up, and on a very different plane from that of its present partisans.

T. D. CROTHERS, M.D.

"A New Operative Method for Exposing the Seminal Vesicles and Prostate for Extirpation"—A Reply.

NEW YORK CITY, June 29, 1901.

To the Editor:—I am very sorry that Dr. Pyle in his letter in the issue of June 15, questioning my claim to originality with reference to the above operative procedure which appeared in THE JOURNAL of May 4, did not incorporate my reply to the letter he had previously sent me on the subject; had he done so I should not now have occasion to continue the correspondence.

On May 24, I received the following communication from Dr. Pyle:

[Copy] "TOLEDO, OHIO, May 23, 1901.

"*Dr. Eugene Fuller, New York:*

"*Dear Doctor:*—I have had the pleasure of reading your article in THE JOURNAL of the A. M. A., upon a supposed "New Method" of removing the prostate gland, etc. I am somewhat surprised to see from New York sources so many slight modifications of the same operation which I performed and fully laid claim to over eight years ago. About every year some surgeon in or about New York brings out a modification of my operation and claims it as his own without even a mention of my publication or claims. This is, indeed, unjust and unprofessional if the facts are known to the new claimants. I hope that you will make known to the readers of the AMERICAN MEDICAL ASSOCIATION JOURNAL that you have advanced no new id.

unless it is changing my dorsal position into a ventral. I have thoroughly covered every claim for the operation which you make and gave this information to the medical profession as early as May, 1892. Look the matter up. I inclose a reprint from the *Philadelphia Medical Journal* that will afford all the data necessary. Very truly,

[Signed] "John S. Pyle."

To the above letter I sent the following reply:

"New York, May 24, 1901.

"*Dr. John S. Pyle:*

"*Dear Sir:*—In reply to your letter I would state that while writing my recent article I was already cognizant of what you had published. As, however, the operative method you reported in 1892 belonged to Zuckerkandl, who first published it in 1889 (*Wein. Med. Presse*), I saw no good reason for mentioning you among the original workers in the field. I really do not see that I have anything to apologize to you for. If I were in your place, however, I should feel like making an apology to Zuckerkandl. Yours truly,

[Signed] "Eugene Fuller."

Dr. Samuel Alexander of this city tells me that some time ago Dr. Pyle wrote him also, complaining that something he (Alexander) had written in connection with perineal prostatectomy encroached on his (Pyle's) operative territory. Dr. Alexander further informed me that he at the time wrote Dr. Pyle, giving references to the literature on the subject which showed that Dr. Pyle's operation was not original with him. Dr. Pyle's photograph in his article which appeared in the *Philadelphia Med. Journal*, April 1, 1899, shows that his incision is an exact copy of the Zuckerkandl incision.

In the light of my letter to Dr. Pyle, and of Dr. Alexander's correspondence with him, it hardly seems to me that that gentleman has any justification in still ignoring Zuckerkandl and in persisting in his claim to originality. In referring to such action, Dr. Pyle in his letter to me states:

"This is, indeed, unjust and unprofessional if the facts are known to the new claimants."

I have given Zuckerkandl full credit in my article for his work. I am perfectly willing to leave to the medical profession the settlement of the question of credit in this connection. If one will try both the Zuckerkandl operation (the one Dr. Pyle does) and the one I have advocated, he will then be in the proper position to see the radical difference between the two procedures. Yours respectfully,

Eugene Fuller, M.D.

Normal versus Decinormal Salt Solution.

Afton, Ind. Ter., June 20, 1901.

To the Editor:—In The Journal of June 15 is a communication from Dr. C. S. Minnich on normal salt solution; he concludes that the solution meant is the "decinormal," not "normal." "Normal" means "the rule," the general average; if a man, a horse, or a cow has the normal number of teeth, it has the number which is the rule for the species; if a man has in his blood-serum sodium chlorid to the amount of 0.6 to 0.8 per cent., then he has the normal amount; normal for a chemist's test solution or reagent, and normal for human blood are two wholly different "normals;" universal agreement could be made whereby the normal and decinormal of the chemist could be changed; but environment has been unable to change the blood serum of terrestrial animals very much from the sea water, which was their original habitat.

Professor Fish, of Cornell, in his recent article on the blood, in the "Reference Hand-Book of the Medical Sciences," places the soluble inorganic salts at 6.4 parts per 1000, "the principal salt is the chlorid of sodium;" (Edition of 1901, vol. ii, p. 35.) Flint, "Physiology," Fourth Edition, p. 21, places the inorganic salts at 6 to 8 parts per 1000. Samuel M. Brinckner, in "Foster's Reference-Book of Practical Therapeutics," vol ii, p. 321, says: "In the serum of the normal (not decinormal) human body sodium chlorid is found in the proportion of 0.6 per cent. This has been named the normal or physiological salt solution." Now, assuming that the general average, the standard, or the *normal* is 0.6 per cent. and the weight of a pint of distilled water at 60 F. is 7291 grains, then 0.6 per cent. is 43.746 grains of sodium chlorid to make a "physiological" or "normal" salt solution; this is 87.5 grains to a quart, which *happens* to be nearly the same as Dr. Minnich's "decinormal" solution of 89.9 grains, but he again proves himself inexact, for 89.9 grains is the amount for a liter, and a liter is 1.0565 of a quart; more, by nearly 6 per cent. Chemical knowledge is a fine thing, but one must not try to impose arbitrary chemical standards on nature, who fixed her "normals" at a time when the memory of man "runneth not to the contrary." Very respectfully,

R. H. Harper, M.D.

The X-Ray in Quackery.

To the Editor:—In the issue of March 2, there was published an interesting editorial headed: "The *X*-ray in Quackery," which was quite prophetic. Here is the essence of a letter sent me by an upright, intelligent physician from Iowa, which explains itself: "Within a few miles from my office lives a priest-physician who claims to have an improved *x*-ray machine by means of which he told a patient that he had an attack of cystitis, and another that he had a cancer in the stomach and that a few nodules had developed within the last ten days, etc."

The physician, who is anxious to do good work and desired to secure the best apparatus to become as perfect a diagnostician as possible, consulted me concerning the possibilities of the *x*-ray. It is scarcely necessary to inform you that I denounced the priest as a quack and assured my medical friend that there is no machine discovered as yet, which can "transform a human being into glass."

The time is not far distant when the following "Ad." will appear in the newspapers:

"The Microscope outlived! By means of our special improved *x*-ray machines, in a few seconds we can watch how your food is digested in the stomach and how the cells in the brain collapse! Do you suffer from indigestion or headache—come to our laboratory—we will let you see yourself as if you were made of glass!"

What a bad world to live in! Barnum was right: The people want to be humbugged—the quacks are accumulating bank accounts, while the scientific and conscientious practitioner is probably worrying how to meet his rent.

This is all abnormal. There are ways and means to crush quackery if the American physicians were united, but that, so far, is an Utopian dream. *Sic transit gloria mundi!*

Respectfully yours,

Gustavus M. Blech, M.D.

The Virchow Fund.

New York City, July 1, 1901.

To the Editor:—Some months ago a committee consisting of Dr. Reed, President of the American Medical Association, Dr. Bowditch, President of the Congress of American Physicians and Surgeons, Dr. Weir, President of the New York Academy of Medicine, Dr. Welch, of Johns Hopkins University, and the undersigned secretary, published an appeal to the American medical profession requesting contributions to the Virchow fund which was established ten years ago in honor of Rudolf Virchow's 70th birthday, which was reached Oct. 13, 1891. The fund was created for the purpose of fostering biological, anthropological and general medical research. A large German Committee, with national committees formed all over the globe, has undertaken to increase this fund in honor of the coming 80th birthday of the great medical reformer.

Whatever contributions will be raised should be sent to Germany on the first day of September in order to be received and acknowledged by the central committee in due time. As our former notices may have been overlooked by such as are anxious to show their appreciation of the great master and to aid the cause represented by his life-long labors, we herewith repeat our appeal.

A. Jacobi, M.D., Secretary,
110 West 34th Street.

Book Notices.

ATLAS AND EPITOME OF THE NERVOUS SYSTEM AND ITS DISEASES. By Professor Dr. Christfried Jakob, of Erlangen. From the Second Revised German Edition. Edited by Edward D. Fisher, M.D., Professor of Diseases of the Nervous System. University and Bellevue Hospital Medical College, New York. With 83 plates and copious text. Cloth, $3.50 net. Philadelphia and London: W. B. Saunders & Company. 1901.

This work has been for some time known to students in its German edition and this authorized translation under the direction of Dr. Fisher will widely increase the knowledge of its advantages. As the Editor says and we can thoroughly agree with him, there is, so far as known, no work in which so much is compressed within so small a space, and it fills a place in the literature that has long needed such filling. The illustrations are well selected and exceedingly good. The explanations are clear and ample. The book is divided into six parts: 1, the morphology of the nervous system; 2, its development in structure and histology; 3, the anatomy and physiology of the more important nerve pathways: 4, general pathology and treatment of diseases of the nervous system; 5, special pathology; it concludes with some remarks on autopsy and microscopic examinations. The book has an excellent though not too extensive index. The translation, so far as we have been able to examine the work, seems to be a satisfactory one; and the book being one of the series known as Saunders' Medical Hand-Atlases, nothing need be said as to the beauty of the illustrations.

ATLAS AND EPITOME OF LABOR AND OPERATIVE OBSTETRICS. By Dr. O. Schaeffer, of Heidelberg. From the Fifth Revised German Edition. Edited by J. Clifton Edgar, M. D., Professor of Obstetrics and Clinical Midwifery, Cornell University Medical School. With 14 lithographic plates, in colors, and 139 other illustrations. Cloth. Price, $2.00 net. Philadelphia and London; W. B. Saunders & Company. 1901.

Outside of anatomy there is no branch of medicine and surgery that is as difficult to demonstrate as that of obstetrics, and it might be said with truth, as regards many colleges, that there is no important part of the physician's duty that is so poorly taught as midwifery. Hence, the young physician, anxious to understand and to be prepared for the various complications in this part of his work, will be more than gratified at the graphic and practical illustrations contained in this little book. These illustrations in colors are works of art, and cover all the various positions, normal and abnormal, and illustrate all the operations in midwifery, including Cesarean section. While sufficient text accompanies the illustrations to explain them, the book is not intended as a text-book; but as a companion to the ordinary text-book on obstetrics it will be a great help to the beginner.

THE EXTRA PHARMACOPEIA. By William Martindale, F.L.S., F.C.S., Late President and Examiner of the Pharmaceutical Society, and W. Wynn Westcott. M.B., Lond., D.P.H., Coroner for Northeast London. Tenth Edition. Cloth. Pp. 688. Price, 10 shillings, 6 pence. London: H. K. Lewis. 1901.

This little book has been brought up to date, including the results obtained through revisions of the various Pharmacopeias since the last edition of the British Pharmacopeia. It is conveniently arranged, and contains all the preparations of the British Pharmacopeia, with references to therapeutic experience from various sources. It embodies a list of the drugs, as well as the sections on antitoxin and organotherapy, analytical memoranda with chemical tests, etc., and a therapeutic index of diseases and symptoms. The journals referred to are largely British, though a few American ones are included. A rather significant and useful table gives the 121 preparations most commonly ordered in the total of 25,000 prescriptions, which forms, as the author says, a therapeutic reflex of British medical practice. The addenda generally are very convenient for reference, and as the preparations of the British Pharmacopeia are often referred to in American medical literature, the usefulness of the work to American readers can be readily appreciated.

ORAL SURGERY. A Text-Book on General Medicine and Surgery as Applied to Dentistry. By Stewart Le Roy McCurdy, A.M., M.D., Professor of Anatomy and Surgery, Pittsburg Dental College. Cloth. Pp. 368. Price, $3.00 net. Pittsburg, Pa.: The Calumet Publishing Co. 1891.

This little volume is intended especially for the "practicing dentist." The author says that "general pathology can in no way differ from pathological changes in the mouth up to a certain period, etc." While the clumsily expressed principle outlined herein is to a certain extent correct, still the subject is treated in a very superficial manner. Special works on general medical subjects for the dental practitioner were once needed, but since the specialty is a department of medicine such works are no longer required. The author offsets unsound dictum by the remark that "some knowledge of all these subjects, however, is necessary." Dental specialists, however, require as much medical training as ophthalmologists, rhinologists, otologists, etc.

The oral surgeon will gain no general knowledge from this book, at least not sufficient to pay for the time lost in its perusal. The oral or dental surgeon is hungry for general pathology and underlying principles, but these must be obtained from standard works upon practice and pathology.

APHORISMS, DEFINITIONS, REFLECTIONS, AND PARADOXES, Medical, Surgical and Dietetic. By A. Rabagliati, M.A., M.D., F.R.C.S. Ed., Late President of the Leeds and West Riding Medico-Chirurgical Society. Cloth. Pp. 291. Price, $2.50. New York: Wm. Wood & Co. 1901.

This work is a series of reflections on medical subjects; largely on the importance of diet and its errors in the production of disease. The author is a neologist from the beginning, though the additions to our language which he makes are not so numerous as they are prominent in this book. It is a thoughtful work that almost any physician can pick up and read with interest, though he may occasionally find some minor point where he may disagree with the author. Nearly all disorders, according to the author's views, arise from errors in the diet; eating too much, or eating too often, or what he calls polysiteism and pollaki-siteism. The book belongs to a class that is perhaps less common at the present time than it was earlier in the history of medicine, but that does not mean that it is a work behind the times. It contains a great deal of valuable matter that is suggestive where it may not be directly instructive, and it often is both.

PATHOLOGY AND MORBID ANATOMY. By T. Henry Green, M.D., F.R.C.P., Physician and Special Lecturer on Clinical Medicine at Charing Cross Hospital. Revised and Enlarged by H. Montague Murray, M.D., F.R.C.P., Physician to Out-patients and Lecturer on Pathology and Morbid Anatomy at Charing Cross Hospital. Ninth American Revised from the Ninth English Edition by Walton Martin, Ph.B., M.D., Assistant Demonstrator of Anatomy, College of Physicians and Surgeons, Columbia University. With 4 colored plates and 339 illustrations. Cloth. Pp. 585. Price, $3.25. Philadelphia and New York: Lea Brothers & Company. 1900.

Green's pathology has been before the student public of this country so long and is so well and favorably known, that a new and thoroughly revised edition should be welcomed. In this volume, the English edition has been thoroughly revised by Dr. H. Montague Murray, a large part of the subject matter rewritten, and the American edition has been edited by Dr. Walton Martin, who has supplied special chapters. The work in its present form deserves to fully retain the favor that it has heretofore received.

A MEDICOLEGAL MANUAL. By William W. Keysor, Lecturer on Medical Jurisprudence in the Omaha Medical College, and Judge of the District Court, Omaha, Neb. Cloth. Pp. 316. Price, $2.00. Omaha: The H. J. Penfold Co. 1901.

This work is the production of a lawyer rather than a physician, and therefore, we may look for some errors on the purely medical side. For example, in defining delusion, the author seems to have a very imperfect appreciation of the meaning of the word. Another instance is in his mention of certain forms of monomania so-called, among which he includes puerperal mania as a disposition of women recently delivered to destroy their offspring. The legal side of the work, however, we can not criticise, and presume that it is correct and reliable as regards special legal points where medical questions are not especially involved, at least as of first importance. While we can not advise it as a perfectly correct and safe manual to follow on medical questions, on other points it may be and probably is satisfactory.

Atlas and Epitome of Obstetric Diagnosis and Treatment. By Dr. O. Schaeffer, of Heidelberg. From the Second Revised German Edition. Edited by J. Clinton Edgar, M.D., Professor of Obstetrics and Clinical Midwifery, Cornell University Medical School. With 122 colored figures on 56 plates, 38 other illustrations, and 317 pages of text. Cloth. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Company. 1901.

This volume is really a companion to the volume referred to above, and all that is said of that volume could be repeated here. The book now before us is, however, more pretentious, is more of a text-book and has a greater didactic value. The illustrations are of the same high order that has characterized this series of Medical Hand-Atlases. The extremely low price at which such books can be sold is possible only from the fact that the plates are used to print not only the series published in this, but a similar series in several other countries.

A Short Practice of Gynecology. By Henry Jellett, B.A., M.D., B.Ch., B.A.O. (Dublin University), F.R.C.P.I., L.M., Late Assistant Master, Rotunda Hospital. With 125 Illustrations. Cloth. Pp. 436. Price, $2.63. London: J. & A. Churchill, Philadelphia: P. Blakiston's Son & Co. 1900.

This work was written, as the author says, for the object of affording a concise account of gynecologic diseases and their treatment. He has certainly condensed within its four hundred and odd pages a large amount of information. He has used material from various sources, both in the selection of illustrations and by consulting authorities. There is nothing theoretic about it; various conditions and operations are described in a brief, concise way, and the illustrations are generally well selected for the purpose of illustrating the conditions. We would not advise it as a text-book to supplant the larger and more thorough works, of which there are so many, but in its small way it will fill a useful place.

A Practical Treatise on Diseases of the Skin, for the Use of Students and Practitioners. By James Nevins Hyde, A. M., M. D., Professor of Skin, Genito-Urinary and Venereal Diseases, Rush Medical College, and Frank Hugh Montgomery, M. D., Associate Professor of Skin, Genito-Urinary and Venereal Diseases, Rush Medical College. Sixth and Revised Edition. Illustrated with 107 engravings and 27 plates in colors and monochrome. Cloth. Pp. 828. Price, $4.50. Philadelphia and New York: Lea Brothers & Co. 1901.

Sufficient evidence of the popularity of this treatise is given by the fact that this, the sixth edition, follows the fifth in practically a year. The authors have taken advantage of the opportunity for further revision of the work and brought it down to date, many of the chapters being entirely or partly rewritten, with the addition of some new plates and engravings.

Obstetrics. A Manual for Students and Practitioners. By David James Evans, M.D., Lecturer on Obstetrics and Diseases of Infancy, McGill University, Montreal, Canada. Series Edited by Bern B. Gallaudet, M.D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, Columbia University, New York. Illustrated with 149 engravings. Cloth. Pp. 430. Price, $1.75. Philadelphia and New York: Lea Brothers & Company.

This is one of Lea Brothers' pocket text-books requiring a rather large pocket, but it appears to be one that will fill a useful place and be a convenient reference handbook on obstetrics. The book is well illustrated and clearly written, and is apparently all that it pretends to be.

Lessons in the Anatomy, Physiology and Hygiene of Infancy and Childhood, for Junior Students. By Alfred C. Cotton, A.M., M.D. Cloth. Pp. 174. Illustrated. Price, $1.50. Chicago: Chicago Medical Book Company. 1901.

This volume comprises extracts from lectures delivered by the author at Rush Medical College, on the anatomy, growth, physiology and hygiene and nourishment, of the new-born, with chapters on milk analysis, weaning, foods, etc. The work is fully illustrated and contains much practical information on the subjects treated.

Eczema, with an Analysis of Eight Thousand Cases of the Disease. By L. Duncan Bulkley, A.M., M.D., Physician to the New York Skin and Cancer Hospital. Third Edition of Eczema and its Management entirely Rewritten. Cloth. Pp. 368. Price, $1.25. New York and London: G. P. Putnam's Sons. 1901.

The third edition shows a vast amount of creditable work, but hardly reaches the standard of the preceding edition. Condensation would have added materially to the value of the volume.

A Compend of Diseases of the Skin. By Jay F. Schamberg, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine. Second Edition. Revised and Enlarged. With 105 Illustrations. Cloth. Pp. 291. Price, $0.80. Philadelphia: P. Blakiston's Son & Co. 1900.

This little work is a successful compilation and a very useful volume to the student.

Married.

C. H. Waite, M.D., to Miss Constance Webber, of Ann Arbor, June 20.

Albert A. White, M.D., Trinidad, Colo., to Miss Bixler, of Denver, June 12.

Charles E. Humiston, M.D., Chicago, to Miss Myrtle J. Wheeler, June 17.

Charles Emil Brack, M.D., to Miss Mary A. Grob, both of Baltimore, June 9.

William E. Burton, M.D., to Miss Blanche V. Dougherty, at Baltimore, June 12.

Herbert W. Rayner, M.D., to Miss S. Lois McChesney, of Minonk, Ill., June 24.

William Albert Nitze, M.D., to Miss Annina Hilken, both of Baltimore, June 8.

John D. Dameron, M.D., to Miss Ella Wheeler, both of Stockton, Cal., June 12.

Herman S. Judd, M.D., Lead, S. D., to Miss Marie Norton, of Topeka, Kan., July 3.

Arnold A. D'Ancona, M.D., to Mrs. Lillian D'Ancona, both of San Francisco, June 10.

John Mann, M.D., to Miss Nannie Caskie Scott, both of Petersburg, Va., June 19.

Carl Raver, M.D., Sacramento, Cal., to Miss Tina Masten, of Ann Arbor, Mich., June 21.

Leslie W. Snow, M.D., to Mrs. Ida Daynes Cannon, both of Salt Lake City, Utah, June 11.

John B. Slicer, M.D., to Miss Eva Cecilia England, at Elkton, Cecil County, Md., June 12.

Percy Louis Kaye, M.D., Philadelphia, to Miss Marie L. Waltham, of Baltimore, June 20.

James Foster Scott, Jr., M.D., to Miss Fannie George, of Blooming Grove, Texas, June 12.

Alfred O. Peterson, M.D., Omaha, Neb., to Miss Eva Newbie Bolshaw, of Lincoln, Neb., June 12.

Alexander J. Slaven, M.D., to Miss Tassie Katherine Ohmer, both of Dayton, Ohio, June 10.

Fred Jackson Jarvis, M.D., Delta, Iowa, to Miss Irene E. Parsons, of Iowa City, Iowa, June 20.

Upton Darby Nourse, M.D., to Miss Alice Windsor, at Darnestown, Montgomery County, Md.

William R. Marsden, M.D., Utica, N. Y., to Miss Rose Olive Stevens, at Whitesboro, N. Y., June 12.

Melvin C. Millet, M.D., Rochester, Minn., to Miss Mary Albertine Frick, of Minneapolis, June 12.

William Bullock, M.D., Grundy Center, Iowa, to Miss Nellie Kessler, of Solon, Iowa, June 19.

Edward T. Burnham, M.D., Wilmington, Del., to Miss Elma Cecilia Sheppard, of Baltimore, June 19.

Fred Harwood Powers, M.D., to Miss Celeste Webb, at Vienna, Dorchester County, Md., June 19.

Theodore Stuart Hart, M.D., to Miss Mary Ayers Wolcott Robbins, both of New York City, June 26.

James Francis McKernon, M.D., to Miss Anna Madeline Wittmeyer, both of New York City, June 26.

Samuel Boyce Craton, M.D., to Miss Annie Fairbanks Hutchinson, both of Syracuse, N. Y., June 12.

William T. Barry, M.D., Salinas, Cal., to Miss Julia V. Morse, of Chicago, at San Francisco, May 28.

Charles A. Sinsel, M.D., Grafton, W. Va., to Miss Mary Davidson, of Taylor County, W. Va., June 19.

William H. Harrison, M.D., Houston, Texas, to Miss Nannie J. Robinson, of Chattanooga, Tenn., at Houston, June 19.

Erasmus Mortimer Garrott, M.D., to Miss Mary Kretzer Adams, both of Sharpsburg, Washington County, Md., June 12.

Harvey Moore Wallace, M.D., Spottswood, Augusta County, Va., to Miss Lucy Waddell Baker, of Staunton, Va., June 5.

Alexander F. Magruder, M.D., a retired naval officer with the rank of inspector, of Washington, D. C., to Mrs. Ida Newton Gulick, of New York, at Baltimore, June 20.

Sidney O. Heiskell, M.D., assistant health commissioner and superintendent of the quarantine station, Baltimore, to Dr. Doralyn Bryan, formerly head nurse at Baltimore University Hospital, at Philadelphia, June 11.

Deaths and Obituaries.

Erastus J. Buck, M.D., Jefferson Medical College, Philadelphia, 1854, who was injured in a runaway accident June 7, died at his home in Platteville, Wis., June 21, aged 72. He was a member of the Wisconsin legislature in 1860-1861, raised a company of sharpshooters in 1861, served as first lieutenant, then resigned to become surgeon, and in this capacity served throughout the war. He had practiced in Platteville since 1868. He was a member of the American Medical Association.

Edwin E. Waite, M.D., Bellevue Hospital Medical College, New York, 1877, a well-known practitioner and some-time physician to the overseers of the poor, and city physician of New Bedford, Mass., died at his home in that city, June 20, from pulmonary hemorrhage, after a long illness, aged 43.

Robert J. Martin, M.D., New York University, 1887, a leading young physician of Augusta, Me., and surgeon of the Second Infantry, N. G. S. M., lost his life, June 16, while endeavoring to save a woman from drowning at Belgrade Lakes, near Augusta. He was 36 years of age.

George W. Beal, M.D., Ohio Medical College, Cincinnati, 1863, a pioneer of Montana, died June 8 at his home in German Gulch, Mont., from shock consequent on injuries received by a fall from his wagon, aged 75. He was mayor of Butte in 1881 and prominent in territorial politics.

Ludwell G. Thacker, M.D., Bellevue Hospital Medical College, New York, 1866, a prominent physician of Northwestern Ohio, and a member of the American Medical Association, died at his home in Defiance, June 20, from consumption, aged 48.

Charles P. Chesley, M.D., Cooper Medical College, San Francisco, 1870, an esteemed practitioner of San Francisco, and a member of the American Medical Association, died June 14, from Bright's disease, after an illness of two years, aged 67.

George Hosmer Magness, M.D., Bellevue Hospital Medical College, New York, 1876, died at his home in White Plains, N. Y., aged 50. He was president of the Health Board, and a member of the Weschester County Medical Society.

William Irving, M.D., Trinity Medical College, Toronto, Ont., 1874, an old and highly respected practitioner of St. Mary's, Ont., died at his home in that place, June 19, from pneumonia following inflammatory rheumatism.

William Conrad Smith, M.D., University of Pennsylvania, Philadelphia, 1850, who had practiced at and around Linglestown, Pa., for more than half a century, died suddenly at his home in that place, June 16, aged 72.

William L. Nichol, M.D., University of Pennsylvania, Philadelphia, 1849, an old practitioner of Nashville, Tenn., and formerly surgeon in the United States Navy, died at his home in Nashville, June 23, aged 73.

Timothy Newell, M.D., Vermont Medical College, Woodstock, 1850, practitioner in Providence for nearly half a century, and a surgeon in the Civil War, died at his home in Providence, June 20, aged 81.

William J. Campbell, M.D., Harvard Medical School, Boston, 1900, house physician at the Worcester City Hospital, died June 14, aged 26, of smallpox contracted from a patient for whom he was caring.

Aaron Lewis, M.D., Indiana Medical College, La Porte, Ind., 1846, for many years a practitioner of Waukegan, Ill., died at the home of his daughter in Louisa, Va., June 24, aged 83.

Andrew F. Wright, M.D., Kentucky School of Medicine, Louisville, 1859, died at his home in Sherman, Texas, where he had practiced for twenty-five years, June 14, aged 76.

Benjamin F. Reynolds, M.D., Jefferson Medical College, Philadelphia, for many years a practitioner of Pittsburg, Pa., died at his home in Hulton, Pa., June 12, aged 67.

Westervelt Banta, M.D., Niagara University, Buffalo, N. Y., 1888, died at his home in Buffalo, N. Y., June 17, from cancer of the stomach, after an illness of two months.

Achbor J. Baker, M.D., University of Michigan, 1886, of Grafton, W. Va., was drowned, June 24, in an ineffectual attempt to save his 8-year-old son from drowning.

William H. Briggs, M.D., Geneva Medical College, Geneva, N. Y., 1844, for many years a practitioner of Rochester, N. Y., died at his home in that city, June 14, aged 79.

Van Buren Dixon, M.D., who was committed to Montevue Hospital for the Insane, at Frederick, Md., February, 1899, died there, June 8, from paralysis, aged 62.

Arthur J. Dresser, M.D., one of the physicians at the State Hospital at Tewkesbury, died at that place, June 11, from typhoid fever, after a long illness, aged 26.

George H. Preston, M.D., New York University, 1879, a practitioner of Kane, Pa., ever since his graduation, died at his home in that place, June 11, aged 45.

Edward L. Groess, M.D., University of Buffalo, 1893, of Buffalo, died at his home in Black Rock, June 19, from paralysis of the heart, aged 38.

Lee Wood, M.D., University of Tennessee, Nashville, 1890, of Abbeville, La., died at Warsaw, Ark., June 14, after a prolonged illness.

Alanson T. Smith, M.D., New York University, 1885, of Brooklyn, N. Y., died at his home in that place, June 17.

James M. Cole, M.D., a charter member of the Winona County (Minn.) Medical Society, died recently.

John Bryan, M.D., an old physician of Cincinnati, died at his home in that city, June 11, aged 75.

Societies.

Baltimore and Ohio Association of Railway Surgeons.—At the annual meeting of this Society, held in Chicago, May 31 and June 1, Dr. Thomas H. White, Connellsville, Pa., was elected president. The next meeting will be held in Atlantic City, N. J., in June, 1902.

Manchester (N. H.) Medical Association.—At the annual meeting of this Society, held June 14, Dr. James S. Brown was elected president; Dr. J. Franklin Robinson, vice-president; Dr. Arthur F. Wheat, secretary; Dr. William H. Pattee, treasurer, and Dr. Walter T. Crosby, pathologist.

Des Moines Valley (Iowa) Medical Association.—The thirtieth annual meeting of this Association was held at Ottumwa, June 20. Dr. France C. Roberts, Fort Madison, was elected president; Dr. Henry C. Eschbach, Albia, vice-president, and Dr. Murdock B. Bannister, Ottumwa, secretary-treasurer.

Dorchester (S. C.) Medical Association.—This Association was organized at St. George, Dorchester County, S. C., June 10, and elected the following officers: Dr. P. L. Horn, St. George, president; Dr. F. Julian Carroll, Summerville, vice-president: Dr. J. B. Johnson, secretary, and Dr. Perry M. Judy, St. George, treasurer.

Hennepin County (Minn.) Medical Society.—At the annual meeting of this Society, held at Minneapolis, June 17, Dr. Henry L. Staples was elected president; Dr. Frank C. Todd, vice-president; Dr. Arthur E. Benjamin, secretary; Dr. William H. Condit, treasurer, and Dr. George D. Head, librarian, all of Minneapolis.

Central District (Iowa) Medical Society.—At the meeting of this Society at Greenwood Park, Des Moines, June 18, Dr. Josiah D. McVay, Lake City, was elected president; Dr. John I. Hostetter, Colo, vice-president, and Dr. George H. Stanger, Boone, secretary-treasurer. The next meeting will be held at Boone in December.

Aberdeen District (S. Dak.) Medical Association.—The fourth quarterly meeting of this Society was held at Aberdeen, June 18. The following officers were elected: Dr. William E. Edwards, Bowdle, president; Dr. Frank Miller, Aberdeen, vice-president, and Dr. George E. Countryman, Aberdeen, secretary and treasurer.

West Chicago Medical Society.—This Society was organized June 18, and the following officers were elected: Dr. Emil D. St. Cyr, president: Dr. Oscar G. Wernicke, vice-president; Dr. George M. Silverberg, treasurer; Dr. Gustavus M. Blech, secretary, and Drs. Arthur M. Shabad, Frederick W. Henkel, Julius M. Abelio and S. Brownstein, executive council.

South Dakota Medical Society.—The annual meeting of this Society was held in Huron June 11 and 12. The following officers were elected: Dr. Cheney C. Gross, Yankton, president; Drs. John Owen Duguid, Springfield, and Byron A. Bobb, Mitchell, vice-presidents; Dr. James L. Stewart, Irene, secretary and treasurer, and Dr. Henry B. Scofield, Scotland, assistant secretary. The Society will meet next year in Scotland.

Alumnae Association of the Northwestern University Woman's Medical School.—The annual meeting of this Association was held at the college, June 20. The following officers were elected: Dr. Annie White Sage, president; Drs. Vira A. Brockway and Catherine Angell Warthern, vice-presidents; Dr. Eliza H. Root, secretary; Dr. Mary Gilruth McEwen, assistant secretary, and Dr. Mary C. Hollister, treasurer.

Alumni Association of the Medical College of the State of South Carolina.—The Association held its annual meeting at the close of the graduation exercises of the college and elected the following officers: Dr. Julius A. Mood, Sumter, president; Drs. Robert L. Brodie, of Charleston, W. D. Ferguson, of Laurens, P. Gourdrin DeSaussure, of Charleston, and O. A. Matthews, of Newberry, vice-presidents, and Dr. C. Bunting Colson, Charleston, secretary and treasurer.

Illinois Association of Military Surgeons.—The annual meeting of this Association was held in Chicago, June 18. Colonel Nicholas Senn, surgeon-general, and Lieutenant-Colonel Charles Adams were re-elected president and secretary, respectively, and Major Thomas J. Sullivan, surgeon Seventh Infantry, I. N. G., was elected vice-president to succeed Major Truman W. Miller, deceased. The Association will hold its next meeting at Moline in October.

American Orthopedic Association.—At the meeting of this Association, held at Niagara Falls, N. Y., May 11, 12 and 13, the following officers were elected: Dr. H. Augustus Wilson, Philadelphia, president; Drs. William J. Taylor and Gwilym G. Davis, Philadelphia, vice-presidents; Dr. John Ridlon, Chicago, secretary, and Dr. Elliott G. Brackett, Boston, treasurer. Philadelphia was chosen as the place for the next meeting in May, 1902.

Maine Medical Association.—The forty-ninth annual meeting of this Association was held in Portland, June 12, 13 and 14. The president, Dr. Edward H. Hill, Lewiston, in his address, considered at length the subject of tuberculosis. The election of officers resulted as follows: Dr. Frederic H. Gerrish, Portland, president, and Drs. Charles E. Philoon, Auburn, and J. M. Willis, Guilford, vice-presidents. The annual oration was delivered by Dr. Edward Reynolds, Boston, on "The Use of Gynecology by the General Practitioner."

Class of 1876 of the Department of Medicine of the University of Pennsylvania.—This body held its first annual banquet at the University Club, Philadelphia, June 11, and effected a permanent organization for the benefit of its alma mater. The following officers were elected: Dr. Charles A. Oliver, president; Dr. William H. Klapp, vice-president; Dr. Francis M. Perkins, secretary, and Dr. Benjamin F. Baer, treasurer, all of Philadelphia, with an executive committee of twelve which will meet at the call of the president.

North Missouri Medical Association.—This Association held its annual meeting at Monroe City, June 20 and 21. The officers for the ensuing year are as follows: Dr. S. M. Brown, Monroe City, president; Drs. W. S. Thompson, Armstrong, and W. G. Yates, Collis, vice-presidents; Dr. Robert Haley, Brookfield, treasurer; Dr. L. W. Dallas, Hunnewell, recording secretary, and Dr. William A. B. McNutt, Monroe City, corresponding secretary. The Association adjourned to meet at Macon City, June 19 and 20, 1902.

Arizona Medical Association.—The most successful meeting ever held by this body was convened in Phoenix on May 22. A large part of the time was used in reading and discussing papers upon the climatology of Arizona, with special reference to tuberculosis, and diseases of the kidneys and bladder. Seventy-six per cent. of the regular practitioners of Arizona are members of the Association. The next meeting is to be held in Tucson, May 21 and 22, 1902. The following officers were elected: Dr. H. W. Fenner, Tucson, president; Dr. H. H. Stone, Phoenix, O. E. Plath, Phoenix, and O. S. Boido, Tucson, vice-presidents; Dr. George M. Brockway, Florence, treasurer, and Dr. Charles H. Jones, Tempe, secretary.

Massachusetts Medical Society.—The 120th annual meeting of this Society was held in Boston, June 11, 12 and 13. The following officers were re-elected: Dr. Frank W. Draper, Boston, president; Dr. William W. Eaton, Danvers, vice-president; Dr. Edward M. Buckingham, Boston, treasurer; Dr. Charles W. Swan, Brookline, corresponding secretary; Dr. Francis W. Goss, Roxbury, recording secretary, and Dr. Edwin H. Brigham, Boston, librarian. Dr. David W. Cheever, president of the Boston Medical Library, presented its claims. On the new building there had been raised and expended $73,000, and there was a mortgage of $50,000. The library needed an endowment for new books, and in addition to a request for this, Dr. Cheever urged the fellows of the society to become associate members, to use the library and to support it.

Buffalo Academy of Medicine.—The annual meeting of the Academy was held June 11. The election of officers resulted as follows: Dr. Charles G. Stockton, president; Dr. Francis W. McGuire, secretary; Dr. Charles S. Jewett, treasurer, and Dr. Matthew D. Mann, trustee. The permanent funds now amount to more than $1300, and it is hoped that the Academy may some day own its building. In his address the retiring president, Dr. Marcell Hartwig, declared that free hospitals and dispensaries had nearly ruined private practice and that hospitals were often hostile to the medical profession. He also complained of persons of wealth patronizing hospitals instead of calling in their family physician. As a remedy he urged that physicians should amalgamate, and build and maintain their own hospitals so that they may be free to act and not be the tools of a lay board of trustees or managers.

Society of the Alumni of the Medical Department of the University of Pennsylvania.—At the annual meeting of this Society, June 11, a portrait of Prof. John Ashhurst, Jr., was presented by the class of 1901, and received by Dr. Frederick A. Packard on behalf of the Board of Trustees. It was announced that the Alumni medal had been awarded to Homer J. Rhode, of Kutztown, Pa. The following officers were elected: Dr. James Tyson, Philadelphia, president; Drs. Horace Y. Evans, Charles K. Mills, Samuel D. Risley and Frederick A. Packard, of Philadelphia, William W. Johnston, of Washington, D. C., Howard Kelly, of Baltimore, Grover W. Wende, of Buffalo, N. Y., and Edward Jackson, of Denver, Colo., vice-presidents; Dr. Roland Curtin, Philadelphia, historian, and Dr. Wm. J. Wadsworth Philadelphia, secretary and treasurer.

Association of American Medical Editors.—The annual meeting of this Association was held at St. Paul, June 3, 4 and 5. At the instance of Dr. Foster, a committee, consisting of Drs. George H. Simmons, editor of The Journal, George M. Gould, of *American Medicine*, and Burnside Foster, of the *St. Paul Medical Journal*, was appointed to amend the constitution and by-laws of the Association by adding certain rules concerning the nature of the advertising to be admitted to the pages of the journals in affiliation with the Association. These rules are to be binding on all members, the committee also being advised to suggest such revision of the constitution and by-laws as may be deemed advisable. The annual dinner of the Association was held June 3, President Stone acting as toastmaster. The officers for the ensuing year are: Dr. Alexander J. Stone, St. Paul, president; Dr. Burnside Foster, St. Paul, vice-president, and Dr. O. F. Ball, St. Louis, secretary and treasurer.

THE AMERICAN PROCTOLOGIC SOCIETY.

Third Annual Meeting, held at St. Paul, Minn., June 4 and 5, 1901.

President Dr. James P. Tuttle, New York City, in the chair.

Malignant Tumors of the Rectum.

The president, **Dr James P. Tuttle**, New York City, delivered the Annual Address on the above subject. He divided malignant tumors into four classes: Connective, epithelial, muscular, and irregular tissue growths.

He described 43 cases from his own practice, and from the literature of the subject; of these 29 of the melanotic type and 14 of the non-melanotic. Sarcomas occur in the rectum as round or elliptical irregular deposits beneath the mucous membrane, sometimes resembling a hypertrophied tonsil. They rarely, if ever, assume the smooth plaque-like form seen in carcinoma, the surface being always rough, unequal, "muriform," and the mucous membrane being movable over the growth in its earlier stages, are conditions which distinguish them from carcinoma. They originate in the submucosa, may appear as sessile tumors, and eventually develop a distinctly polypoid shape. They may also appear as a general fibrous thickening of the wall and be mistaken for simple inflammatory stricture. The mucous membrane covering sarcomas is comparatively normal, although if the tumor becomes very large, the membrane may become congested, edematous, or ulcerated, and even adherent to the growth through inflammatory processes. Sarcomas in the rectum are either single or multiple, and vary in size from a hazel nut to a good-sized orange. Sarcomas of the rectum present a variety of colors, generally that of the normal mucous membrane, although sometimes they are dark red, grayish-black, bright red, pale-yellowish pink, or as black gangrenous masses. Often in the multiple form, the different tumors will present varying appearance. Sarcomas may occur at any portion of the rectum or sigmoid, but the majority are situated low down near the anal margin. Sarcomas differ from carcinomas by their rapid growth. Unlike sarcomas in other portions of the body, these sarcomas are said to have a distinct tendency toward ganglionic infection. Metastasis is one of the chief characteristics of sarcomas of the rectum. If the growth be primary, all possibility of metastatic deposit should be eliminated, or else the operation will be of no avail. A complete résumé of the histology was given under the following heads: Round or globe-cell sarcomas, spindle or fusiform, giant cell, alveolar, and mixed. Melanosis does not alter the type of the tumor or change the character of its component parts. It takes place in all types and may involve but one part of a tumor, or only one or two tumors where they are present in multiple form. Sarcomas of the intestine always develop from the submucosa, and ordinarily affect the mucous membrane only after pressure, tension, and ulceration, through friction and infection by fecal masses. The causes and influences which bring about the production of sarcoma are as little known as those of carcinoma. Age cannot be proved to have any direct influence, although the disease occurs more often late in life, and there is apparently no relationship between the sexes and this disease. Symptoms are at first very vague. There may be a sense of fullness, or the feeling of the presence of a foreign body, or the first symptom may be bleeding and discharge of mucus. The protrusion of sarcomatous tumors is more frequent than in case of carcinoma, but less so than in other forms of rectal neoplasms. There is no odor peculiar to sarcoma. After ulceration has occurred and there is a production of pus, the odor changes to that of decomposing tissue, but never assumes that peculiar characteristic odor which is found in carcinoma of the rectum. If the sarcoma is low down and involves the sphincter, producing traction and pressure, the patient may suffer considerable pain. But if it is high up and of an infiltrating form the patient may go to the very door of death without any knowledge of its existence. The state of the bowels in sarcoma of the rectum varies according to the type of the tumor. There may be either constipation or diarrhea. The latter may be caused by the mobility of the growth and its location near the margin of the anus. Constipation may be caused upon mechanical grounds. Flatulence, indigestion, and loss of appetite are associated with sarcoma of the rectum as they are with all other neoplasms of this organ. Cachexia is not well marked. Reflex digestive disturbances are noted. Decrease in strength, loss of flesh, swelling of the feet and abdomen rapidly succeed one another, when the sarcoma is once well developed. Dysuria is frequently present. The lungs and pleura may become affected.

The diagnosis of this condition lies between carcinoma, and villous tumor. The tumor is less sessile than carcinoma, and less pedunculated than adenoma. It is more firm than adenoma and has a less degree of induration than carcinoma. In its attachment, its roots do not spread out, producing that general infiltration of the mucous membrane that obtains in carcinoma. Its attachment is very abrupt. To the touch it is more undulating and irregular than carcinoma, but has not the granular and dendritic divisions which one finds in villous tumor and in adenoma. The latter occurs largely in children whereas sarcoma is a disease of middle or advanced life. When it is a question between sarcoma and multiple adenoma, the multiplicity of the growths, the excessive diarrhea, together with the comparatively fair condition of the patient's health, may be mentioned upon the side of adenoma. Between sarcoma and carcinoma, the distinct odor of the latter is enough to make the decision positive. In the early stages of the disease, the fact that the mucous membrane moves easily over the growth distinguishes it almost positively from carcinoma. The final test depends upon the microscopic examination of a section from the real substance of the tumor itself. Personally the essayist was opposed to making an incision to obtain the section unless the case was operable and the patient consented to an operation if the microscopic examination showed a necessity for one.

The treatment of the disease consists in the radical removal of the growth. A ligature to pedunculated sarcomas ought never to be considered. If the growth is single and in the wall of the rectum a posterior proctotomy may be done. If it is diffuse, involving the entire circumference of the rectum, total excision of the organ is the only recourse. While there is some evidence of the value of the serum therapy in the treatment of the sarcomas elsewhere, the advocates of this method lend no encouragement by their results in the treatment of this condition in the rectum. Artificial ani may give great relief in carcinoma, but it neither relieves nor checks the progress of sarcoma.

Disease of the Sigmoid.

Dr. G. B. Evans, Dayton, Ohio, discussed the question as to whether or not the rectum was the receptacle for feces, or whether the latter is arrested, detained, and accumulated in the sigmoid flexure of the colon. The reader inclined to believe that the rectum was the receptacle. From its situation and anatomical relations, the reader was convinced that the sigmoid is oftener the seat of obscure abdominal diseases than has generally been suspected. In appendicitis there is often reflected pain over the whole abdomen, often in the left iliac region over the sigmoid. Now if this is true, the converse is also true. This point was illustrated by reference to a patient who had a distinct history of appendicitis. The condition was promptly relieved by flushing the sigmoid and colon with large quantities of hot boric solution. This treatment was advised in all cases of supposed appendicitis. It can do no harm and might do good.

Recto-colitis.

Dr. William M. Beach, Pittsburg, Pa., described recto-colitis as a condition of the rectum and colon that generates functional derangements consequent upon varying degrees of inflammation of its mucous membrane. Omitting mal'g diseases, recto colitis was considered under the following

Congestion, atrophic catarrh, hypertrophic catarrh, and ulceration. Simple congestion due to engorged blood-vessels may be ephemeral and express itself locally in the form of dysentery and tenesmus and the excretion of an enormous quantity of mucus. This condition if allowed to continue becomes chronic, developing usually the hypertrophic catarrh; epithelium is shed, valves swollen and thickened, narrowing of rectal straits, diarrhea alternating with constipation. Atrophic catarrh is usually accompanied by the constipated habit; dry hard stools, and minute anal fissures. Secretions are insufficient on account of gland impairment. Atrophic recto-colitis is rare. The ulcer is the culmination of the inflammatory process, and in the experience of the reader rarely occurs above the sigmoid flexure.

Anal Pockets.

Dr. Louis J. Krouse, Cincinnati, first entered into a very exhaustive study of the so-called anal pockets in which he gave the results of his own observations and those of other investigators. He discovered by his researches that these pockets were present in the rectums of the living to the extent of 80 per cent., but that they were entirely absent in the dead. In conclusion he said: That the so-called anal pockets may be the cause of certain diseases located in the lower outlet of the bowel, I cannot gainsay; but I believe that they are most likely the frequent predisposing cause of an irritable ulcer of the anus. If we examine the rectum in the quiescent state, when the bowels are empty, we find that the anus is closed; the anal valve and its corresponding sac are absent. But when the bowels move, the anal canal is opened and the anal valve becomes prominent, the same as would occur had an anal speculum been introduced and opened. Should a hardened fecal mass pass through the anal outlet, with a prominent pseudovalve protruding, then this valve would most likely be caught by the moving mass and possibly be torn, producing what might be termed an irritable ulcer of the anus.

The Treatment of Rectal Prolapse.

Dr. J. Rawson Pennington, of Chicago, believes that some of the most important factors in the production of rectal prolapse are to be found within the intestinal canal and considers the plica transversalis recti et sigmonideæ as one of the most, if not the most, important causative factors. He continued by saying that various procedures have been devised for the treatment of this malady, but to be successful the operation selected must be determined by the variety and specific conditions of the prolapse, otherwise it will be a failure. Of these procedures he mentioned, 1, those having for their object the production of adhesive inflammation between the coats of the intestinal walls; 2, narrowing the anal canal; 3, amputation; 4, reposition and bony fixation; 5, reposition and intra-abdominal fixation (colopexy or sigmoidopexy); 6, Thuré Brandt massage; 7, electricity; 8, ligature.

New Method for the Removal of Hemorrhoids Under Local Anesthesia.

Dr. Thomas Charles Martin, Cleveland, stated that nonmalignant anal growths could be removed painlessly without resort to general anesthesia by means of a technique which he described, provided it be performed by the trained hands of an operator who thoroughly understands the principles of infiltration anesthesia, and who, furthermore, has been sufficiently persevering to master the difficulties encountered in the application of those principles to this operation.

The following officers were elected to serve during the coming year: Dr. Thomas Charles Martin, Cleveland, president; Dr. George J. Cook, Indianapolis, vice-president; Dr. William M. Beach, Pittsburg, secretary-treasurer, and Drs. Joseph M. Mathews, Louisville, Ky., James P. Tuttle, New York City, and J. Rawson Pennington, Chicago, executive committee. Prof. Dr. Sonnenberg, Berlin, was elected to honorary membership on motion of Dr. William M. Beach, Pittsburg. The Society will meet at Saratoga, N. Y., in June, 1902.

Sun Baths for Chronic Eczema.—*Winternitz* reports the cure of a number of cases of chronic eczema with sun baths, the chemical rays arrested by red clothing.

PHILADELPHIA PATHOLOGICAL SOCIETY.

President, Dr. F. A. Packard, in the Chair.

Some Unusual Types of the Tubercle Bacillus.

Dr. M. P. Ravenel made some remarks on unusual types of the tubercle bacillus, to show the variability of this organism when grown upon different culture media. One of the growths was very greasy in appearance. In this specimen staining was very difficult. The specimen was derived from a goat suffering with the disease. If, as some contend, the pathogenicity depends upon the amount of fat contained, this special culture should be highly virulent, which did not seem the case. In other cultures of this micro-organism the cultures appeared greenish or blackish. In later instances the specimens were obtained from a child suffering with tubercular peritonitis.

Dr. A. C. Abbott spoke of the work of Dr. Trudeau, who had also referred to certain peculiarities exhibited by the tubercle bacillus. In regard to the cultures presented he thought they looked like mould. He was under the impression that the work done by the speaker not only demonstrated the variability of the tubercle bacillus, but also its different microchemic reactions. It might appear that certain cultures of this micro-organism in the lower animals were pathogenic, while others were not so. The different characteristics of this micro-organism might be due to a difference in their environment.

Variola.

Dr. W. M. Welch and Jay F. Schamberg presented specimens from a case of variola. The patient had been admitted to the Municipal Hospital on May 5, and was 28 years of age. He had never been vaccinated. When admitted the disease had advanced to the 5th day of the eruption. Death had occurred on the 12th day. The specimen of affected skin had been removed from the upper surface of the thigh and pubes. It vividly showed the papules and umbilicated vesicles present in this condition. At the autopsy the stomach had been found intensely congested, almost hemorrhagic, the veins being prominent, while the esophagus was quite pale, although a few minute ulcerated spots were found. Cultures of the heart blood were made and showed numerous streptococci.

The Increase of Connective Tissue in the Lung in Chronic Passive Congestion.

Dr. R. M. Pearce referred to the various changes which had been noted in the parenchyma and interstitial tissue. He had made certain investigations using the Weigert stain, resorcin, fuchsin, sesquichlorid of iron, and passing through alcohol, and xylol. Congo red, and eosin and carmin were also found of value. He had studied the bronchi, pleura, and septa, and found that the elastica diminished gradually until it reached the terminal bronchioles. At the vestibule the elastica was found collected in distinct nobs, or nodules, where it was thickened and stained irregularly. In some sections the tissue seemed to be made up of blood vessels and elastica. The greatest increase was in the bronchi. The increase in the blood-vessel walls was in the adventitia.

Dr. Simon Flexner thought that the results obtained demonstrated the improvements which had recently been made in micro-chemic technic. The increased rigidity of the lungs in chronic congestion might be explained from this increased amount of elastica present.

Probable Primary Intestinal Tuberculosis in an Adult with Metastases.

Dr. F. A. Packard, in detailing the clinical history, stated that the man had been a laborer, 30 years of age, who had died at the Pennsylvania Hospital May 17. He had been ill for several days with vomiting and diarrhea. The temperature had been 101, pulse 72. Nystagmus was also present. Plantar reflexes were increased, and Kernig's sign was marked. Lumbar puncture had been done, but no fluid obtained. No eruption had been present. It was thought that meningitis was present in this case. The specimens were exhibited to show that the primary focus might probably have been in the intestine.

Dr. Simon Flexner spoke of the results found at autopsy. The left lung was firmly adherent to the chest wall, and adhesions were also present between the lung and pericardium. In the lung gray tubercles were found. The bronchial lymph glands were enlarged and contained caseous material. Sections of the lung were pale, and miliary tubercles were present. There were no cavities present. The intestines were distended, and along its coats miliary tubercles were found. Tubercles were found in the pelvis. The blood vessels of the bladder were injected. The vermiform appendix was enlarged, the serous membrane injected and covered with miliary tubercles. The mesenteric glands were enlarged and caseous. The adrenals were caseous, as were the retroperitoneal glands. The kidneys showed tubercles. A very large tubercle was found at the base of the brain, and tubercles were present on the ependyme. Tubercles were found microscopically in the meninges at the base of the brain. In this locality the blood vessels showed proliferation of the endothelium.

Dr. W. M. Coplin referred to a form of intestinal tuberculosis mentioned by French writers, and called the hypertrophic form. In certain of these cases, an excision had been done, resulting in a cure. They were of a chronic nature, and the growths resembled that of cancer with ulceration and cicatrization.

Teratoma of the Testicle.

Dr. W. F. Hendrickson read a paper and presented specimens of teratoma of the testicle. The specimen had been removed from a man 25 years of age, and had involved the testicle and a portion of the cord. Two excrescences had been found externally, and adjacent to one, yellowish spots had been present. The testicle was entirely destroyed and replaced by the tumor mass composed of grayish or yellowish-white material. Microscopically the tumor showed a perivascular growth having a peculiar arrangement. About the smaller blood vessels a few giant cells were found, while other cells were of an epithelioid nature. A few giant cells were present near areas of cartilaginous tissue. In certain respects it resembled adrenal material.

Tuberculosis of the Heart.

Drs. W. S. Wadsworth and W. F. Hendrickson presented a card specimen. In this case death had been sudden. At the autopsy cavities were found in the lungs, and the pericardium contained blood-stained serum. The right auricle and ventricle seemed normal. In the left ventricle were found numerous irregular grayish or reddish nodules varying in size from a pinpoint to several millimeters. These growths were also found on the intra-ventricular septum. Microscopically they were identified as miliary tubercles. No tubercle bacilli were present in any of the nodules examined.

NINTH GERMAN CONGRESS OF GYNECOLOGY.

Held at Giessen, May 29-31.

Loehlein in his opening address remarked that atmocausis, angiotripsy and serum-therapy have not yet fulfilled anticipations, and that further experiences are necessary with each.

Carcinoma Uteri.

W. A. Freund delivered the principal address on the above subject. He was able to report only two cases permanently cured in his twenty-three years of experience: one operated on for recurrence after amputation of the portio, the other for carcinoma of the cervix with a nodule in the uterus. Both patients are entirely healthy, seventeen and twenty-three years after total extirpation. He urges that the abdominal route should not be reserved exclusively for the severest cases, as on this account, it is impossible to compare the statistics of abdominal and vaginal operations. Winter claims that the only criterion of the superiority of an operation is the number of permanent cures achieved by it, always bearing in mind the co-efficient of operability. He learned, by inquiry in the various clinics of Germany, that the average mortality after abdominal extirpation with removal of the larger portion of the parametrium and the glands, is 24.6 per cent., with a record of 41.6 per cent. recurrences during the first year. Consequently he believes that the vaginal route is the operation of the future. He makes a Schuchardt vaginoperineal incision in every case. This incision starts from the perineum, is carried across and far back of the rectum, through the entire side of the vaginal wall. It allows ample access to the parametrium. Staude incises on both sides. Olshausen reports 38 per cent. permanent recoveries—that is, the patients cured for more than five years by vaginal extirpation.

Eclampsia.

The second day was devoted to this subject. None of the various theories in regard to the etiology of eclampsia can be definitely accepted, Fehling observed. Schmoral stated that he had found a characteristic anatomic picture at the autopsies of 73 eclamptic women. Schuchardt considers the anemic and hemorrhagic necrosis of the liver highly characteristic. Dienst reported that a circulus vitiosus evidently exists between mother and fetus; the same alterations in the organs are noted in each. He removed a fragment of the liver from an animal with young. It was seized with convulsions soon after. The young were born dead, and the typical eclamptic alterations, especially the liver necrosis, were found in them likewise. Strassmann stated that the experiences at the Berlin Charité indicate that compression of the ureters has some share in the production of eclampsia. The severity of the cases seems to be decreasing of late. Large cities are most affected; social conditions and even the weather, seem to have an influence on its prevalence.

Winternitz stated that he had found the streptococcus in the uterus in 63 per cent. of all his cases of puerperal fever; the staphylococcus in 6; bonococci in 6.3, and the colon bacillus in 3.1 per cent. Leopold exhibited cultures of blastomycetes originally derived from tissue taken from the neighborhood of a carcinoma. He announced that he was able to produce sarcomata as well as carcinomata in animals inoculated, and suggests that the former may be a benign form of the latter. He exhibited a rat with multiple tumors from inoculation of his cultures. Fraenkel reported that the ovary not only produces the ovum, but has a direct influence on its insertion. Hallan also confirmed the fact of the internal secretion of the ovary, stating that he had restored menstruation in monkeys after extirpation of the ovaries, by transplanting an ovary, and that the menstruation was again arrested if the transplanted organ was removed.

Amann described a new extraperitoneal method of abdominal extirpation of the uterus. He remarked that he had observed two cases in which the glands in the posterior wall of the abdomen became carcinomatous more than five years after total vaginal extirpation. His mortality with the latter has been 4 per cent. in 175 operations. By his new method it is possible to remove extensive portions of the parametrium, expose the ureters, bladder-wall and vagina as freely as desired, and yet not open the peritoneum for more than a few minutes. He has been very much pleased with the results in fourteen cases; his first was operated on in April, 1899. The ureters are exposed through a lateral incision, detached, and the uterine or hypogastric artery ligated. The peritoneum is not opened until this is done. Then it is incised, the uterus extirpated through it, and the peritoneal cavity closed again at once by suturing the vesical peritoneum to the peritoneum of the posterior pelvic wall. The parametrium is then exposed and removed as desired, with the glands, terminating with gauze drains in the vagina and abdominal wound. This method allows easy access to the point where the uterine artery and the ureter cross, allowing the implantation of the latter in the bladder if necessary.

The next congress will be held at Wuerzburg, in 1903, with Hofmeier as president. The subjects announced for discussion are "Extra-uterine Pregnancy," and "Plastic Operations with Special Regard to Their Permanent Results."

ONTARIO MEDICAL ASSOCIATION.

The Twenty-first Annual Meeting, held at Toronto, June 19 and 20, 1901.

The president, Dr. Angus McKinnon of Guelph, *in the chair.*

Three Recent Gall-Stone Cases.

Dr. William Oldright, of Toronto, said these cases had occurred recently in his practice. They present features of interest to the profession. The first case occurred in a woman about 55 years of age. The late Dr. Little had seen the patient and had endeavored to obtain purgation, without effect. Powerful cathartics were unavailing. About nine months previously she had a similar attack, but Dr. Oldright had heard nothing about it until this attack. The symptoms were somewhat elevated temperature, about 100 to 101, constant vomiting, obstruction, and intense pain. He supplemented Dr. Little's catharsis, but without any effect. On examination, he could map out a distinct tumor, and told her that she had a distended gall-bladder; advised her to go into the hospital, which she did that night. She was operated on in the afternoon, and removed some gall-stones, and endeavored to establish patency of the duct. He could feel no stones left behind, but there was some stenosis of the duct. There was a great deal of inflammatory action in this case. The gall-bladder was stitched into the abdominal wall and drainage established in the usual method; bile flowed freely. Patient made a good recovery. The second case was one in consultation with Dr. McLean, of Woodbridge. She was 65 years old. The prognosis was certainly death without operation. At the operation he could not locate the gall-bladder. He came to the conclusion that it was not a case for further interference. Within twenty-four hours she succumbed to the shock and probably to some hemorrhage. There was no doubt after passing the finger in, that it was malignant. If this woman had been operated on some years before, Dr. Oldright thought that malignancy would not have occurred, and her life would have been saved. The third case occurred in a woman 40 years of age. Here was a case in which there had been gall-stone symptoms, obstruction, for about eighteen months. She consented to an operation. The obstruction was in the cystic duct. He opened the gall-bladder and took out the stones. The operation occupied about forty minutes. The patient made an uneventful recovery, and left the hospital thirteen days after the operation.

Excision of Upper Jaw for Sarcoma.

Dr. Herbert A. Bruce, of Toronto, presented this paper, whilst Dr. G. Silverthorne exhibited the specimen. Dr. Bruce also presented the patient, a woman, 34 years of age, from whom he had removed the upper jaw for sarcoma. During the last week of January of this year she felt for the first time a slight swelling over the alveolus of the left jaw, which she thought to be a gum boil. She consulted Dr. Bowles at the end of March, and Dr. Bruce saw her about the middle of April, that is, less than three months after the first symptoms. He operated upon her on April 29, exactly three months after the first symptom. On examination, he found a very hard swelling just behind the second bicuspid tooth and extending backwards to the full extent of the jaw. Internally, it had not extended to the middle line, but bulged externally to the extent of half an inch beyond the line of the teeth. It extended backwards towards the antrum, but the latter did not seem to be implicated externally. The growth in the roof of the mouth was covered by a mucous membrane. On looking into the nose, a polypoid mass was seen; and the patient had difficulty in breathing through the left nostril. The cheek on the affected side was slightly more prominent, and it moved freely over the growth. A small portion of the growth was removed under cocain, and Dr. Silverthorne reported to Dr. Bruce that it was sarcoma. The patient left the hospital on May 18 and made an uninterrupted recovery.

Dr. Silverthorne presented the specimen to the members of the Association. It was the size of a large-sized orange, containing spindle cells with a cartilaginous basis.

Ectopic Gestation.

Dr. R. W. Garratt, of Kingston, said the subject is one of vital importance to every practitioner, for at any time he might be called upon to differentiate the condition from others from which it might be confounded. The responsibility of a life was in his hands and demanded accurate diagnosis, medical acumen and judgment and ability to conduct the case to a favorable termination. He entered at considerable length as to the causation and earlier changes consequent upon ectopic gestation, and stated, that every physician is expected to make a correct diagnosis of tubal pregnancy on the occurrence of rupture; and in a fairly large proportion of cases, to make a diagnosis before the occurrence of rupture.

Theoretically, the arrest of a fructified ovum may occur first in the ovary; second, in the abdominal cavity, between the ovary and tube; third, within the tube, and fourth, between the tube and the uterus. He would direct the attention of his audience to but one kind only—arrest within the tube, or tubal pregnancy, as all other varieties are but mere developments of this kind, owing to secondary invasion of the Fallopian tube.

Dr. J. F. W. Ross thought that we ought to be able to diagnose these cases before rupture had taken place. He referred to the pain that is indefinite, not severe; not acute, but a feeling as if something were wrong. He referred to several cases recently seen in practice.

Dr. Powell referred to a case where Dr. Ross had diagnosed these conditions before rupture had occurred.

President's Address.

Dr. Angus McKinnon considered that it was a great honor to be elected president of this, the largest and most influential medical association in the Dominion of Canada. Having referred to the success of the meeting so far, he proceeded to contrast the state of medicine at the beginning of the last century with that of the present, and compared the last advantages we to-day possess over those of one hundred years ago. He deplored the growth in the employment of new, proprietary remedies, and thought that harm was being done to the medical profession by manufacturing firms making up pills for neuralgia, for malaria, etc. He considered that the literature and drugs sent out to medical men by these manufacturing houses had become an intolerable nuisance. The electric-belt man, the "Christian scientist," the advertising cancer-curer, the osteopath, and many other such like takes, which hang on to the skirts of medicine he scored most unmercifully, and regretted that the public press, both secular and religious, opened their columns freely to these fulsome, untruthful, and sometimes immoral advertisements—because they pay well. There was great danger to the public in permitting "Christian scientists," the "pray-for-hire-healers," and the "Dowieites," impudently undertaking to cure infectious diseases such as diphtheria, scarlet fever, and smallpox, diseases which they are unable to recognize; and we think that we have come to a point where toleration and forbearance become criminal. The 2500 medical men in Ontario should have influence enough to obtain from the legislature an amendment to the medical act that will put an end to this trifling with human life. He directed attention to the delay that occurs in securing admission to the asylums for people, the subject of acute mania, and thought that it was high time the necessary steps in this department in the practice of medicine should be simplified.

Vaccinal Protection Against Smallpox.

Dr. P. H. Bryce, of Toronto, the Secretary of the Provincial Board of Health, presented this paper. In the introduction he expressed the belief that, although the practice of vaccination against smallpox has existed for a century, there never was a time since it was formally accepted by the profession, when there was so much expressed skepticism on the part of the laity with regard to its protective qualities, and never a time when the profession has been so indifferent as to impressing the necessity of its proper performance upon the public. In Ontario, between 1898 and 1899, there were but 22 recorded deaths from the disease. He made special reference to the art of vaccination and the quality of the lymph, and thought five separate insertions should be made in each case. The quality of the lymph was very important. He thought that a medical man going out from college did not receive sufficient practical instruction on this most important subject.

Dr. I. H. Cameron discussed Dr. Bryce's paper and stated, as a matter of fact, he had no hesitation whatever in seeing a case of smallpox himself, nor would he object to any member of his family seeing it, if he knew that they had sufficient protection in vaccination. He warned the profession against laxity in dealing with this most important subject.

Dr. Harrison, of Selkirk, stated that he had had considerable experience with smallpox, and on account of that experience he entered a vigorous protest against the prevailing carelessness in insisting on vaccination and re-vaccination in the laity as well as the profession.

Empyema.

Dr. **Ferguson**, of London, said that the treatment of this condition was essentially surgical, and that the medical aspects of the disease were limited to a consideration of its pathogenesis and prophylaxis. He considered that the conditions of non-purulent or primary effusion, indispensable to an understanding of the pathogenesis of empyema. He gave a description of the pleura and discussed the bacteriological aspect of purulent pleurisy, which he divided into four classes; 1, those due to pneumococci; 2, those due to streptococci (and staphylococci); 3, those to the bacilli of tuberculosis; and 4, those caused by saprogenic organisms. In nine cases, extending over eleven years in his practice, three were diagnosed tubercular, three meta-pneumonic, two due to the streptococci, and one undetermined. The prognosis varies with the microorganism present, the pneumococci being the most benign. It is the only variety of purulent empyemia that may possibly yield to treatment by mere aspiration, especially in children. Tubercular empyema is usually mixed infection. The prognosis here will depend upon the general condition of the patient, and the character of the mixed infection. We, therefore, see the importance of a bacteriological examination. As in any other debilitating disease, supporting and tonic treatment is essential. With the advent of pus, surgical means must be adopted.

Dr. J. L. **Turnbull**, of Goderich, said that when the presence of pus is determined it should be evacuated at once, as there is always the danger of the abscess bursting into or through the chest wall, or even through the diaphragm, and producing peritonitis. Aspiration need not be described; remember not to remove the fluid too rapidly. In this, as in an ordinary abscess, it is not necessary to open at the most dependent point. The preferable way, and the one which Dr. Turnbull always uses when a diagnosis of pus is made, is to remove a portion of a rib; an inch and a half may be cut out, preferably with the saw, under strict antiseptic precaution. Dr. Turnbull advises washing out every day when pus is offensive; and drainage tube gradually shortened until it can be removed altogether. Where a cavity and sinus remains after this operation, the sinus may become closed and a second empyema established. This requires an Estlander's operation, and one of the best ways is to carefully locate size and boundaries of cavity with a probe, and after dissecting up a flap of skin to be sure to remove enough bone. The hard fibrous tissue beneath the ribs, which is always present in quantity there, must be thoroughly removed. Dr. Turnbull advises mopping out with pure carbolic acid, then with alcohol, to prevent poisoning, and then with sterilized water, the part being carefully dried. He puts a drainage tube in the most dependent part.

Open Treatment of Disease.

Dr. George H. **Carveth**, of Toronto, described his method of treating different forms of disease: 1, in the house with wide-open windows; 2, in beds on the veranda; 3, in beds under tents on the lawn. At first he experienced some difficulty in getting his patients to consent to be treated in this manner, but after they had become habituated to life in the open air, they returned in-doors reluctantly. Some of the cases that he has treated in this way are iritis, cases of fracture, cases of the radical cure of hernia, rheumatoid arthritis, tubercular disease of the spine, typhoid fever, and a case of hysterectomy. His address was illustrated by lantern slide projections on the canvass, which proved very interesting to the members of the association.

Gastric Ulcer.

Dr. R. D. **Rudolf**, of Toronto, gave a short historical sketch of the chief literature of the subject, and said during the last 30 years only one important symptom had been added to those mentioned by previous writers: the very common occurrence of hyperchlorhydria. Avoiding the consideration of the well-known points on the subject, he propounded five questions in connection with gastric ulcer which seemed to him to specially merit discussion: 1, is there any relation between gastric ulcer and cancer? Trosseau believed that an actual antagonism existed between the two conditions, while Bebert considered that 9 per cent. of all gastric cancers so arose, and Rosenheim states that 5 to 6 per cent. of all gastric ulcers became carcinomatous. Clinically, the speaker had never seen a case of simple ulcer end in cancer, nor had he seen a case of cancer preceded by ulcer, although such cases undoubtedly occasionally occurred.

Dr. **Henry Howitt**, of Guelph, first took up the procedures for dealing with the ulcer or its results, in which perforation is not a factor. In all the operative procedures it was essential to prevent infection of the wound; stomach should be thoroughly washed with aseptic water, by means of siphon tube, immediately before the anesthetic is administered. It is not necessary to make the abdominal incision extensive, the length of the incision would depend upon the amount of contraction, and it is sutured in such a manner that when closed the line of union is at right angles to the original incision. This gives excellent results when properly done. Adhesions render this ideal operation impracticable. The first successful operation in Canada was performed in Toronto, in 1894, by Dr. Atherton. Up to last September in the neighborhood of 300 operations were reported, with a mortality of a little over 45 per cent. Dr. Howitt then referred to cases in his own practice.

With regard to the treatment, Dr. Howitt said that as soon as we are satisfied that perforation has taken place, referring to acute cases, he believes it is good practice to give morphia hypodermically; and it further lessens the amount of the anesthetic in the opinion of many. Success largely depends on the shortness of time before operation; delay is dangerous. It is Dr. Howitt's practice to eviscerate the bowels; one or more small incisions in the prominent coils soon overcomes the distention, and each one is closed before another is made. Attention is now turned to the stomach and the part brought into the wound. The ulcer is incised and opening closed with two or three layers of sutures. When the trouble is in the posterior wall it may be impossible to excise it, in which case, it can be generally inverted and closed by layers of sutures. The abdominal cavity should be thoroughly flushed with a stream of saline solution. When drainage is necessary, the tubes or gauze should not be introduced through a large wound. The object should be to have primary union to take place in the incision.

Resolution of regret for non-payment of the annual $2.00 fee of the Ontario Medical Council was introduced by Dr. Ferguson, of London, seconded by Dr. Gibson, of Belleville, that some members of the profession in the province had refused payment of this annual fee.

This Association regards the imposition of this fee as most reasonable, payment of which should meet with a cheerful response on the part of every member of the profession. This was carried unanimously amid much applause, and without a dissenting voice.

Dr. Wishart, Toronto, chairman of the special committee to draw up a resolution on vaccination, presented the following:

Resolved, That the Ontario Medical Association desires hereby to reassert the opinion of the medical profession of this province.

1. That the principles of Jennerian vaccination against smallpox, which have been now attested by the experience of more than a century, are scientifically correct.

2. That in order to carry out the protection through vaccination against smallpox it is necessary that the lymph used in the operation be of normal quality, and that this can be shown only by a proper amount of systemic reaction to the vaccine, as determined by the character of the vesicles, and that the absence of a normal reaction, as shown by the presence of vesicles, is no positive evidence of the immunity of the person either against vaccinia or smallpox.

3. That this Association emphasizes the urgent necessity that the scarification of the skin be sufficiently extensive to secure such reaction, and to this end recommend that from three to five insertions each of a quarter of an inch square be made in each vaccination.

This was carried.

Medical Defense Union.

On motion of Dr. J. F. W. Ross, seconded by Dr. A. Primrose, a committee was appointed to inquire into this matter, to report at the next meeting of the Association in 1902.

The following officers were elected: President, Dr. N. A. Powell, Toronto; first vice-president, Dr. R. Ferguson, London; second vice-president, Dr. R. W. Garrett, Kingston; third vice-president, L. C. Prevost, Ottawa; fourth vice-president, R. L. Turnbull, Goderich; general secretary, Harold C. Parson, Toronto; assistant, Dr. George Elliott, Toronto; treasurer, Dr. A. R. Gordon, Toronto.

Miscellany.

Military Precautions Against Yellow Fever in Cuba.

The military orders recently issued for the protection of the garrisons in Cuba from yellow fever differ widely from those in force heretofore. Formerly when a case of this disease was discovered in a command the patient was immediately isolated or sent to a yellow fever hospital; the barrack-room from which he was taken was temporarily vacated for a thorough cleansing and disinfection and quarantine was instituted against the locality from which the infection was supposed to have been imported. New cases occurring within five days were regarded as due, like the first, to imported infection, and cleansing and disinfection were again resorted to; but new cases occurring after the lapse of five days led to the opinion that the barracks had become infected and that a dangerous local outbreak of the disease would follow unless checked by disinfection and immediate removal to a new camp site, with a second change of camp site if needful to shake off the infection.

Now, however, the measures enjoined by the military authorities have in view the prevention of the dissemination of the yellow fever infection by mosquitoes. Well men are to be protected from the bites of infected mosquitoes and patients suffering from the fever are to be protected that uninfected mosquitoes may not become infected. Disinfection of rooms, clothing, bedding, etc., is declared unnecessary except in so far as it aims to destroy infected insects that may be present. The following circular was issued April 27, 1901, from headquarters, Department of Cuba, General Leonard Wood, commanding. General Orders No. 6, mentioned in the circular, directed the enforcement of the use of mosquito bars and the destruction of the larvæ of the mosquito by petroleum in all collections of standing water in the vicinity of military stations:

Upon the recommendation of the Chief Surgeon of the Department, the following instructions are published and will be strictly enforced at all military posts in this Department: The recent experiments made in Havana by the Medical Department of the Army having proved that yellow fever, like malarial fever, is conveyed chiefly, and probably exclusively, by the bite of infected mosquitoes, important changes in the measures used for the prevention and treatment of this disease have become necessary. 1. In order to prevent the breeding of mosquitoes and protect officers and men against their bites, the provisions of General Orders No. 6, Department of Cuba, Dec. 21, 1900, shall be carefully carried out, especially during the summer and fall. 2. So far as yellow fever is concerned, infection of a room or building simply means that it contains infected mosquitoes—that is, mosquitoes which have fed on yellow fever patients Disinfection, therefore, means the employment of measures aimed at the destruction of these mosquitoes. The most effective of these measures is fumigation, either with sulphur, formaldehyde or insect powder. The fumes of sulphur are the quickest and most effective insecticide, but are otherwise objectionable. Formaldehyde gas is quite effective if the infected rooms are kept closed and sealed for two or three hours. The smoke of insect powder has also been proved very useful; it readily stupefies mosquitoes, which drop to the floor and can then be easily destroyed. The washing of walls, ceilings and furniture with disinfectants is unnecessary. 3. At it has been demonstrated that yellow fever cannot be conveyed by fomites, such as bedding, clothing, effects and baggage, they need not be subjected to any special disinfection. Care should be taken, however, not to remove them from the infected rooms until after formaldehyde fumigation, so that they may not harbor infected mosquitoes. Medical officers taking care of yellow fever patients need not be isolated; they can attend other patients and associate with non-immunes with perfect safety to the garrison. Nurses and attendants taking care of yellow fever patients shall remain isolated, so as to avoid any possible danger of their conveying mosquitoes from patients to non-immunes. 4. The infection of mosquitoes is most likely to occur during the first two or three days of the disease. Ambulant cases—that is, patients not ill enough to take to their beds and remaining unsuspected and unprotected, are probably those most responsible for the spread of the disease. It is, therefore, essential that all fever cases should be at once isolated and so protected that no mosquitoes can possibly get access to them until the nature of the fever is positively determined. Each post shall have a "reception ward" for the admission of all fever cases and an "isolation ward" for the treatment of cases which prove to be yellow fever. Each ward shall be made mosquito-proof by wire netting over doors and windows, a ceiling of wire netting at a height of seven feet above the floor, and mosquito bars over the beds. There should be no place in it where mosquitoes can seek refuge, not readily accessible to the nurse. Both wards can be in the same building, provided they are separated by a mosquito-tight partition. 5. All persons coming from an infected locality to a post shall be kept under careful observation until the completion of five days from the time of possible infection, either in a special detention camp or in their own quarters; in either case, their temperature should be taken twice a day, during this period of observation, so that those who develop yellow fever may be placed under treatment at the very inception of the disease. 6. Malarial fever, like yellow fever, is communicated by mosquito bites, and, therefore, is just as much of an infectious disease and requires the same measures of protection against mosquitoes. On the assumption that mosquitoes remain in the vicinity of their breeding places, or never travel far, the prevalence of malarial fever at a post would indicate want of proper care and diligence on the part of the Surgeon and Commanding Officer in complying with General Orders No. 6, Department of Cuba, 1900. 7. Surgeons are again reminded of the absolute necessity, in all fever cases, to keep, from the very beginning, a complete chart of pulse and temperature, since such a chart is their best guide to a correct diagnosis and the proper treatment.

High Praise for Senn's Book.

Dr. Juan Redondo, chief surgeon of the Spanish fleet in the Spanish-American War, publishes a long and most flattering review of Dr. Senn's book, "The Medico-Surgical Aspects of the Spanish-American War," in the *Diario de la Marina*, of Madrid, May 6. The following extracts show the high esteem in which the book is held by the reviewer:

"It is very possible that the general sanitary inspections of the war and navy departments of the United States, in their reports and annual statistics, have given a minutely detailed account of the medical happenings of the campaign. But if such works exist, I for my part do not know them, and the truth is that the book of Dr. Nicholas Senn is the first work of this nature truly serious which I have received. * * * He has had opportunities to write a book which, although referring only to the military operations of the Antilles, embraces the matter completely in its military and naval aspect, whose merits I can judge perhaps better than anybody else on account of my being the only Spanish doctor, or may be, of any other nationality, who after fighting in a vessel—and I employ the word in the true sense in which a naval doctor can and should employ it—fought afterwards on land during three months as doctor of the battalion formed with what remained of the crews of an unfortunate fleet. This book which I propose to make known among the medical men of our country's army and navy, if as I hope the author will allow me to translate into Spanish, is edited with an abundance of details and the richness of engravings which Americans use sometimes in this class of work, and artistically considered is a marvel. But high as its value is on this account, its real merit is not there, but in the abundance of matter which it studies, in the multitude of observed facts, in the experiences that can be derived from it, in the highly scientific principles of its author and in the high and liberal spirit with which all its matters are treated. * * * He does not allow himself to be carried away by unreflecting enthusiasm that breed so many errors with many American writers. As a correct and elegant writer he must have taken special pains not to wound our patriotic sentiments when in a book of nearly 400 pages I only find half a dozen words which could pain us, and which if a second edition were made it would be easy for him to change by others which without altering the sense might lessen the cruelty of the expression. This can be of easy accomplishment, since more than once he calls the conduct of our admirals heroic, praises the devotion of our sailors and soldiers to their chiefs, judges in a very flattering manner the chivalry of the military doctors with whom he became acquainted in Santiago, and praises beyond measure a Spanish military surgeon who in Porto Rico nobly attended an American volunteer who, far from his people, was a victim of sunstroke and found completely abandoned in the field. I congratulate Dr. Senn on having written his interesting book, but may not finish without giving him my opinion, contrary to his, when he sustains a point with which I can not in any way accept. I have nothing to say of the motives his nation has had the first four times she has appealed to the supreme argument of arms, but must protest with all the energy of my soul against his branding as strangers in America those who knew how to give an impulse and bring forth to the realities of life the immense continent which was formerly lost in the farthest solitudes of a tempestuous and unknown ocean, and against his saying that the United States when obliging us to go to war with them were exclusively obeying a sentiment of humanity."

Association News.

Section Papers—Non-Members

To the Editor:—I have received a number of communications from members of the Association in which complaint was made that they could not get an opportunity to read their papers at the recent meeting at St. Paul. We have every reason to believe that the meeting to be held at Saratoga from June 10 to 13, 1902, will be one of the largest in the history of the Association, and that the Sections will at a very early date be filled by members applying for permission to read papers. It is a fact well known that every year certain men read papers before several of the Sections. This is not their fault, since they are invited to do so by different Section officers, but it should be understood that if a man has accepted an invitation in one Section he should not accept an invitation to occupy any time in another Section, and as an act of justice to the larger number I would earnestly call the attention of the chairman of each Section to this matter. I would also ask attention to the necessity of being careful not to permit any names to appear upon the program of the meeting of those who are not members of the AMERICAN MEDICAL ASSOCIATION. If a careful scrutiny is made of the list as the names come before the chairman of each Section, and if in case of doubt in regard to the standing of any applicant, information should be requested from the regular organization of the county in which he resides, the facts could be readily obtained and much embarrassment avoided.

Sincerely yours,
JOHN A. WYETH, President.

Portrait of Dr. N. S. Davis.

Through the courtesy of Mr. Charles S. Raddin, chairman of the Museum and Library Committee, the portrait of Dr. N. S. Davis, painted by Zan D. Klopper, of Chicago, has been loaned to and placed in the Chicago Academy of Sciences, and is labeled as follows: "Portrait of Dr. N. S. Davis, President American Medical Association, 1864-65. Loaned by the Association." Offers to furnish the portraits of other ex-presidents of the Association have been received.

J. R. PENNINGTON,
Chairman of Committee on Portraits of Ex-Presidents.

Minutes of the Sections.

Section on Hygiene and Sanitary Science.

TUESDAY, JUNE 4—AFTERNOON SESSION.

A paper on "State Supervision of Marriage; Its Feasibility, Scope, Justification, Possibilities," by Dr. W. H. Heath, of Buffalo, N. Y., was read by Acting Secretary Dr. J. Neely, of Chicago. It was discussed by Dr. Egbert, of Philadelphia; Dr. Liston H. Montgomery, of Chicago; Dr. Tuckerman, of Iowa; Dr. Ferd C. Valentine, of New York City.

WEDNESDAY, JUNE 5.

"Pulmonary Fearlessness," was read by Dr. William T. English, of Pittsburg.

"Limitation of Venereal Diseases," was read by Dr. Denslow Lewis, of Chicago, and discussed by Dr. Ferd C. Valentine, of New York; Dr. Howard A. Kelly, of Baltimore; Dr. Toper; Dr. Reed, of Wyoming; Dr. Tuckerman; Dr. Egbert; Dr. Fuller, of Iowa; Dr. Shrader; Dr. Montgomery, of Chicago, and closed by Dr. Lewis.

THURSDAY, JUNE 6—MORNING SESSION.

"Tuberculosis in the Middle States, and Its Curability," by Dr. John A. Robison, Chicago, was read by Dr. Montgomery, of Chicago.

"Tuberculosis Sanitaria," by Dr. C. P. Ambler, of Asheville, N. C., was read by Acting Secretary Dr. Neely, of Chicago.

"Tuberculosis of Animals in Some of Its Relations to Human Tuberculosis," was read by Dr. D. E. Salmon, Washington, D. C.

"The Experience of Syracuse, N. Y., with the Compulsory Tuberculin Test of all Dairies Furnishing Milk to the City," was read by Dr. B. S. Moore, Syracuse, N. Y.

"The Climatology of Arizona with Reference to the Treatment of Pulmonary Tuberculosis," was read by Dr. R. W. Craig, Phoenix, Ariz.

"Tuberculosis in Its Relation to the Welfare of the People of the United States in General and Colorado in Particular," by Dr. Wm. M. Danner, of Denver, Colo., was read by Dr. H. M. Bracken, of Minneapolis, Secretary of the Board of Health.

The above papers were discussed by Dr. Houghton, of Detroit, Mich.; Dr. Salmon, of Washington, D. C.; Dr. M. H. Reynolds, St. Anthony Park, Minn.; Dr. Norman Bridge, Los Angeles, Cal.; Dr. H. M. Bracken, Minneapolis, Minn.; Dr. B. S. Moore, Syracuse, N. Y.

Section on Stomatology.

TUESDAY, JUNE 4—3 P. M.

The Section was called to order by the Chairman, R. R. Andrews, Cambridge, Mass., at 3 p. m., in the Ladies' Ordinary of the Hotel Ryan.

Committee on Transactions reported that 1000 copies had been printer at a cost of $159.51, and distributed among dental and medical colleges.

The Committee on Education reported progress.

The president then delivered his annual address.

The regular program was then taken up with a Symposium on State Boards of Dental Examiners in their Relation to the Profession and the Colleges. The first paper was by Wm. Carr, New York City, on the subject of "Methods of Appointment: 1, by State Universities, New York; 2, by State Boards of State Officials ex-officio, Nebraska; 3, by Governors on Recommendation of the Profession." The paper was read by the secretary. Two papers were read by the secretary, for Geo. L. Parmele, Hartford, Conn., and V. E. Turner, Raleigh, N. C., on the subject of "Revenue for Conducting the Work of the Boards of Examiners: 1, by Taxation of the People; 2, by Fees from Examination of Candidates; 3, by Taxation of the Profession." The next paper was by Charles Chittenden, Madison, Wis., "The Dental College Standard: 1, Is it What it should be? 2, If Not, What Improvements should be made? 3, How May the Requirements be Improved?" The last paper on the program was on the subject of "Licensing: 1, by Examination; 2, by Diploma;" by J. A. Libby, Pittsburg, Pa. The papers were discussed by Drs. Talbot, Latham, Nones, Andrews, Dennis, Peck, Keoms and Chittenden.

On motion of Dr. Peck, the Section adjourned until 2 p. m., June 5.

WEDNESDAY, JUNE 5—2 P. M.

Section was called to order by the Chairman.

The following papers were read in a Symposium on Degeneracy of the Pulp: "Preliminary Work," by Eugene S. Talbot, Chicago; "Literature of the Pulp," by Vida A. Latham, Rogers Park, Ill.; "Cutting, Staining, and Mounting," by Martha Anderson, Moline, Ill. The symposium was discussed by Drs. R. R. Andrews, G. V. I. Brown, E. S. Talbot, and Vida A. Latham.

Dr. Alice Steeves, for the Nominating Committee, reported the following nominations for officers of the Section for the ensuing year: Chairman, A. H. Peck, Chicago; Secretary, Eugene S. Talbot, Chicago. Members House of Delegates, G. V. I. Brown, Milwaukee; and A. E. Baldwin, Chicago.

A paper on "Infectious Diseases" was read by Dr. Alice Steeves, Chicago, and was discussed by Drs. Latham, Bush, Carpenter, Baldwin, Kiernan, Brown, Andrews and Steeves.

"Periods of Stress and their Dental Marks" was the subject of a paper by Dr. Jas. G. Kiernan, Chicago. The paper was discussed by Drs. Talbot, Latham, Brown and Kiernan.

Dr. G. V. I. Brown, Milwaukee, read a paper on "Surgical Treatment of Cleft Palate." It was discussed by Drs. Kiernan, Wylis, Carpenter and Brown.

THURSDAY, JUNE 6.

Section was called to order at 2 p. m., by the chairman.

The first paper was by M. H. Fletcher, Cincinnati, on "The Tongue as a Breeding Place for Bacteria." The paper was read by the secretary, and was discussed by Drs. Talbot, Brown and Baldwin.

"Military Dental Practice: its Modifications and Limitations." by Henry D. Hatch, New York City, and read by Dr. Baldwin. The subject was discussed in a paper by Dr. John S. Marshall, of Washington, read by the secretary. The paper was also discussed by Drs. Brown, Baldwin, Lyon, Orton, Chittenden Weirick, Latham, Talbot and Andrews.

Dr. G. V. I. Brown, Milwaukee, offered the following resolution, which on motion was unanimously adopted:

Resolved, That the secretary be instructed to write to Dr. John S. Marshall conveying to him the congratulations of this body upon his appointment, upon his paper and upon the excellent manner in which the committee has laid out the preliminary work it has undertaken, and assure him of our earnest support in that work.

"Simple Gingivitis" was the subject of a paper by Dr. Geo. T. Carpenter, of Chicago, and was discussed by Drs. Brown, Talbot, Latham, Baldwin, Carpenter and Andrews.

Adjourned *sine dic.*

Section on Nervous and Mental Diseases.

Tuesday, June 4—Afternoon Session.

The meeting was called to order by Dr. H. A. Tomlinson, of St. Peter, Minn., Chairman.

Address of Chairman.

"Etiology of Paretic Dementia," by Dr. Frank P. Norbury, of Jacksonville, Ill. Discussion by Drs. Harold N. Moyer, of Chicago; E. G. Carpenter, of Columbus; Richard Dewey, of Wauwatosa, Wis.; Sidney Kuh, of Chicago; E. E. Mayer, of Pittsburg, and H. A. Tomlinson, and Frank P. Norbury.

"Symptomatology of Cerebral Hemorrhage" was read by Dr. F. Savary Pearce, of Philadelphia. Discussion by Drs. Hugh T. Patrick, of Chicago; F. W. Langdon, of Cincinnati; John Punton, of Kansas City; W. A. Jones, of Minneapolis; E. G. Carpenter, of Ohio, and F. Savary Pearce.

"What Can Be Done for the Epileptic in a Medical Way?" was read by Dr. R. H. Porter, of Chicago. Discussed by Drs. Lambert Ott, of Philadelphia; John Punton, of Kansas City; Hugh T. Patrick, of Chicago; C. Eugene Riggs, of St. Paul; Dr. Sexton, of Kansas City; F. Savary Pearce, of Philadelphia; E. E. Mayer, of Pittsburg; Warner, and Drew, of Massachusetts, and R. N. Porter, in closing.

Wednesday, June 5—Afternoon Session.

"The Treatment of the Acute Psychoses in Private Practice" was read by Dr. C. Eugene Riggs, of St. Paul, Minn. Discussion by Drs. Richard Dewey, of Wisconsin; John Punton, of Kansas City; Frank P. Norbury, of Jacksonville, Ill.; C. A. Drew, of Massachusetts; O. Everts, of Cincinnati; J. G. Biller, of Cherokee, Iowa; F. W. Langdon, of Cincinnati; M. B. Sexton, of Kansas City; F. Savary Pearce, of Philadelphia; Harold N. Moyer, of Chicago; H. A. Tomlinson, of Minnesota; James G. Kiernan, of Chicago, and E. Riggs, in closing.

A Symposium on Syphilis of the Brain consisted of "Nervous Manifestations," by Dr. Hugh T. Patrick, of Chicago; "The Psychosis in Cerebral Syphilis," by Dr. Richard Dewey, of Wauwatosa, Wis.; and "Syphilis of the Nervous System; Its General Pathology, with Remarks on Treatment," by Dr. F. W. Langdon, of Cincinnati. Discussion by Drs. C. B. Burr, of Flint, Mich.; H. D. Valin, of St. Peter, Minn.; E. G. Carpenter, of Columbus; John Punton, of Kansas City; E. E. Mayer, of Pittsburg; Sydney Kuh, of Chicago; Frank P. Norbury, of Illinois; and closed by Drs. Dewey and Langdon.

"Suggestions for Lessening the Frequency of Relapse After Treatment for Morphinism," was read by A. J. Pressey, of Cleveland, and discussed by Drs. T. D. Crothers, of Hartford, Conn.; John Punton, of Kansas City; Frank P. Norbury, of Illinois; Lambert Ott, of Philadelphia; and A. J. Pressey, in closing.

"Injuries, Feigned and Real, with Their Differentiation and Medicolegal Aspect," was read by Lambert Ott, of Philadelphia, and discussed by Drs. Harold N. Moyer, of Chicago; Leo M. Crafts, of Minneapolis; Richard Dewey, of Wisconsin; J. G. *Biller*, of Iowa; Herman Gasser, of Platteville, Wis.; F. Savary Pearce, of Philadelphia; Dr. Leaming, of Chicago, and closed by Dr. Ott.

On motion of Dr. Frank P. Norbury, a message of sympathy was sent to Dr. J. T. Eskridge, of Denver, Colo., who was detained at home by illness.

Thursday, June 6—Morning Session.

"Treatment of Neurasthenia" was read by J. G. Biller, of Iowa. and discussed by Drs. Hugh T. Patrick, of Chicago; McBride, of California; John Punton, of Kansas City; C. Eugene Riggs, of St. Paul; Harold N. Moyer, of Chicago; F. Savary Pearce, of Philadelphia; H. A. Tomlinson, and J. G. Biller.

"The Psychoses of Chorea" was read by Dr. Harold N. Moyer, of Chicago, and discussed by Drs. Riggs, of St. Paul; E. G. Carpenter, of Ohio; Edward E. Mayer, of Pittsburg; and John Punton, of Kansas City.

"Three Cases of Paralysis of the Serratus Magnus and the Trapezius: Alar Scapula," was read by Dr. Augustus A. Eshner, of Philadelphia, and discussed by Dr. Pearce, of Philadelphia.

"Mirror Writing and Inverted Vision" was read by Dr. Albert B. Hale and Sydney Kuh, of Chicago, and discussed by Drs. Sweeney, of St. Paul; Richard Dewey, of Wisconsin; Herman Gasser, of Wisconsin; and S. Kuh, in closing.

Thursday, June 6—Afternoon Session.

"Ten Cases of Acute Infectious Multiple Neuritis" was read by Dr. W. A. Jones, of Minneapolis, and discussed by Drs. Patrick, of Chicago; H. N. Moyer, of Chicago; and W. A. Jones, in closing.

"Fear as an Element of Nervous Diseases, and Its Treatment," was read by Dr. John Punton, of Kansas City. "A Case of Localized Amnesia, with Remarks Thereon," was read by Dr. Edward E. Mayer, of Pittsburg. Discussion by Drs. T. D. Crothers, of Hartford; McBride, of California; Riggs, of St. Paul; Moyer, of Chicago; Jones, of Minneapolis; Pearce, of Philadelphia; and Mayer.

"Dementia Following Inebriety" was read by T. D. Crothers, of Hartford, and discussed by Drs. C. A. Drew, of Massachusetts, and T. D. Crothers, closing the discussion.

"The Importance of Heredity as a Cause of Insanity" was read by Dr. Arthur McGugan, of Michigan, and discussed by Drs. Mayer, of Pittsburg; Dewey, of Wisconsin; Crothers, of Connecticut; Drew, of Massachusetts: Drayton, of New York: *Joseph F. Robinson*, of Nevada, Mo.; Pearce, of Philadelphia: Tomlinson, and McGugan.

The Chairman announced that under the provisions of the reorganization scheme it becomes necessary for each Section to elect two delegates. This must be done at this session, as the House of Delegates will convene at the beginning of the next meeting of the Association.

Dr. Hugh T. Patrick, of Chicago, said it was designed that the retiring Chairman should be one of the two delegates. Moved and carried that the Chairman be selected as a Delegate.

Dr. W. A. Jones, of Minneapolis, moved that the selection of the second Delegate be left to the Nominating Committee. Carried.

Report of the Nominating Committee: Dr. Patrick, the Chairman of the Nominating Committee, reported that Dr. J. T. Eskridge, of Denver, had been selected as Chairman for the next year. As Dr. Eskridge is in poor health, and may not be able to attend the meeting on that account, Dr. Richard Dewey, of Wauwatosa, Wis., had been selected as Alternate. Secretary, Dr. F. Savary Pearce, of Philadelphia.

It was moved and seconded that the report of the Nominating Committee be accepted. Carried.

Dr. Harold N. Moyer, of Chicago, was selected as the second member of the House of Delegates, to serve for two years.

"Persistent Brachial Neuralgia from Hypodermic Injection—Incipient Amyotrophic Lateral Sclerosis, with Recovery," was read by Dr. Leo M. Crafts, of Minneapolis.

Section on Cutaneous Medicine and Surgery.

First Day, June 4.

Address of Chairman, W. L. Baum, on "Ancient and Modern Conceptions of Syphilis."

"Pathology and Treatment of Cutaneous Cancer, with Special Reference to Its Non-Parasitic Nature," was read by Dr. M. L. Heidingsfeld. It was discussed by Drs. W. T. Corlett, W. A. Pusey, E. L. Schmidt, Joseph Zeisler, Burnside Foster, D. W. Montgomery, D. Lieberthal, C. W. Allen, A. W. Brayton, and M. L. Heidingsfeld.

"Syphilis and Its Relations to Blastomycetic Dermatitis" was read by Dr. Henry G. Anthony. It was discussed by Drs. J. Nevins Hyde, F. H. Montgomery, Joseph Zeisler, A. W. Brayton, R. R. Campbell, M. Herzog, F. H. Montgomery, and H. G. Anthony.

"Notes on a Case of Keratosis Follicularis (Porospermosis)" was read by Dr. Joseph Zeisler, and discussed by Dr. F. H. Montgomery.

The Chairman appointed as Nominating Committee, Drs. Corlett, of Cleveland; Anthony, of Chicago; and Sumney, of Omaha.

It was moved and carried that the Chairman appoint a committee of three to draft a Constitution and By-Laws for the Section, to be reported at the next annual meeting. Carried.

Second Day, June 5.

Dr. Burnside Foster, of St. Paul, presented a Case of Lupus Erythematosis, One of Congenital Nevus Pigmentosus. He also reported a case of Leprosy in a man who had never been outside of Minnesota. These cases were discussed by Drs. Zeisler, D. W. Montgomery, *Corlett, Bulkley, Schuler, and Frick.*

The Nominating Committee reported Henry W. Stelwagon, of Philadelphia, for Chairman, and R. R. Campbell, of Chicago, for Secretary. Elected by unanimous vote.

"Lantern Slide Demonstration on Skin Cancer," by Dr. M. L. Heidingsfeld, of Cincinnati, was discussed by Drs. F. H. Montgom*ery and J. Nevins Hyde.*

J. Nevins Hyde and F. H. Montgomery demonstrated "Blastomycosis of the Skin" with lantern slides. Discussion was by Dr. Joseph Zeisler, Chicago.

Dr. W. T. Corlett, of Cleveland, demonstrated, by lantern slides, "The Exanthemata." Dr. S. Pollitzer, New York City, read a paper on "Smallpox."

Dr. David Lieberthal, of Chicago, discussed "Phototherapy in Cutaneous Medicine."

A paper by Dr. L. E. Schmidt, of Chicago, on "Epidermolysis Bullosa Hereditaria," was discussed by Drs. M. L. Heidingsfeld and F. H. Montgomery.

A paper on "Epithelioma of Long Duration," by Dr. William Frick, of Kansas City, was discussed by Drs. M. L. Heidingsfeld and Anthony.

Third Day—June 6.

A paper on "Rhinoscleroma," was read by Dr. Charles Warrenne Allen (by invitation), New York City, and discussed by Drs. J. Nevins Hyde, and D. Lieberthal, of Chicago; Hall, of Kansas City, and Charles W. Allen.

Drs. Charles W. Allen, of New York City, and W. L. Baum, of Chicago, were elected delegates to the House of Delegates.

Dr. David Lieberthal read a paper on "Lichen Hypertrophicus." It was discussed by Drs. Wm. Frick, Kansas City; Charles W. Allen, New York City; D. W. Montgomery, San Francisco; H. G. Anthony, Chicago; W. T. Corlett, Cleveland; L. Duncan Bulkley, New York City; R. R. Campbell, Chicago; H. C. Sumney, Omaha; M. L. Heidingsfeld, Cincinnati. and D. Lieberthal, Chicago.

A paper on "Notes on Recent Cases of Extra-genital Chancre," was read by *Dr. L. Duncan Bulkley, New York City, and discussed* by Drs. Baldwin, Chicago; E. L. Schmidt, Chicago; Montgomery, San Francisco; Charles W. Allen, New York City; R. R. Campbell, Chicago; D. Lieberthal, Chicago; W. T. Corlett, Cleveland, and L. Duncan Bulkley.

A case of dermatitis herpetiformis, in a physician, was demonstrated.

The Section adjourned *sine dic.*

Section on Laryngology and Otology.

Tuesday, June 4—Afternoon Session.

The Section was called to order at 2:30 p. m.

There being no committees to report, the first order of business was the "Address of Chairman," by Dr. John N. Mackenzie, of Baltimore, Md.

Two members of the Executive Committee being absent, the Chairman appointed two members to fill the vacancies. The Committee was then as follows: Emil Mayer, of New York City; W. E. Casselberry, of Chicago, and J. E. Logan, of Kansas City, Mo.

The Chairman stated that the reading of papers would be limited to twenty minutes and discussions to five minutes, and that papers not present when called would be deferred until all papers on the program for the session were called, and if not reached would then take their place at the end of a succeeding session.

The Chairman appointed Dr. C. M. Cobb, of Lynn, Mass., on the Banquet Committee.

"The Treatment of Laryngitis" was read by Dr. O. T. Freer, of Chicago, and discussed by Drs. E. Fletcher Ingals, of Chicago; Robert Levy, of Denver, and the Essayist.

"Edematous Laryngitis, with Report of Case," was read by Dr. J. S. Gibb, of Philadelphia.

"Total Extirpation of Thyroid Gland" was read by Dr. G. F. Cott, of Buffalo, and discussed by Dr. J. Holinger and the Essayist.

The Chair appointed the following Nominating Committee: E. Fletcher Ingals, of Chicago; S. E. Solly, of Colorado Springs, and Emil Mayer, of New York City.

Wednesday, June 5—Morning Session.

The first paper read was "Types of Membranous Pharyngitis," by Dr. W. E. Casselberry, of Chicago. It was discussed by Drs. Emil Mayer, of New York City; B. R. Shurly, of Detroit; Emil Amberg, of Detroit; J. Holinger, of Chicago, and the Essayist.

"The Relation of the Middle Turbinate Body to Chronic Nasal Diseases" was read by Dr. C. S. Baker, of Bay City, Mich., and discussed by Drs. J. F. Barnhill, of Indianapolis; W. E. Casselberry, of Chicago; G. O. Woolen, of Indianapolis; C. M. Cobb, of Lynn, Mass.; D. A. Kuyk, of Richmond, Va.; E. Fletcher Ingals, of Chicago; Emil Mayer, of New York City; J. Holinger, of Chicago, and the Essayist.

"Asthma as a Result of Nasal Conditions. Treatment, etc.," was read by Dr. J. A. Farren, of Chicago, and discussed by Drs. G. N. Jack, of New York; J. F. Barnhill, of Indianapolis, and Farren, in closing.

"An Unusual Anomaly Affecting the Faucial Tonsil," by Dr. George L. Richards, of Fall River, Mass., was read by Dr. C. M. Cobb, of Lynn, Mass. "The Effect which the so-called Catarrhal Disease of the Nose and Throat may have upon the General Health" was read by Dr. C. M. Cobb, of Lynn, Mass., and the papers by Drs. Richards and Cobb were discussed by Drs. W. E. Casselberry, of Chicago; G. O. Woolen, of Indianapolis; L. C. Cline, of Indianapolis; D. Roy, Atlanta; D. A. Kuyk, of Richmond, Va.; O. T. Freer, of Chicago; J. A. Farren, of Chicago, and C. M. Cobb, in closing.

Wednesday, June 5—Afternoon Session.

The Section members convened at 2:15 p. m.

The report of the Nominating Committee was received through Dr. Emil Mayer, recommending as officers of the Section: Dr. G. Hudson Makuen, of Philadelphia, as Chairman, and Dr. J. F. Barnhill, of Indianapolis, as Secretary. On motion, the Secretary cast the ballot of the Section for the election of the officers named.

On motion by Dr. E. Fletcher Ingals, of Chicago, the Section proceeded to the election of a Committee on Nominations. The following nominations of committeemen were made: Drs. E. Fletcher Ingals, of Chicago; W. E. Casselberry, of Chicago; O. T. Freer, of Chicago; C. M. Cobb, of Lynn, Mass.; S. Johnston, of Baltimore.

The Chair appointed as tellers Drs. Dickerman and Jackson. On the first ballot Drs. Ingals and Cobb were declared elected. There was a tie vote between Drs. Casselberry and Johnston. Drs. Casselberry and Johnston withdrew their names, and Dr. Casselberry nominated Dr. G. Hudson Makuen, of Philadelphia. On motion the Secretary cast the ballot of the Section for the election of Dr. Makuen.

"Empyema of the Frontal Sinus" was read by Dr. E. Fletcher Ingals, of Chicago. "Anomalies of the Frontal Sinus and their bearing on Chronic Suppurative Sinusitis," by Dr. Redmond W. Payne, of San Francisco. The papers by Drs. Ingals and Payne were discussed by Dr. Edward T. Dickerman, of Chicago, and closed by Drs. Ingals and Payne.

"Carcinoma of the Naso-Pharynx" was read by Dr. Chevalier Jackson, of Pittsburg, Pa.; "Sarcoma of Nasal Passages, with Report of Cases," by Dr. Dunbar Roy, of Atlanta, Ga.

Dr. E. Fletcher Ingals, of Chicago, reported, for the Committee on Nomination, the following nominations for members of the Nominating Committee: Drs. Emil Mayer, of New York City; George C. Stout, of Philadelphia; W. E. Casselberry, of Chicago; J. E. Logan, of Kansas City, and E. T. Dickerman, of Chicago. On ballot the following were elected a Nominating Committee: Dr. Emil Mayer, of New York City, for two years, and Dr. George C. Stout, of Philadelphia, for one year.

"Case of Epithelioma Involving the Tonsil, Faucial Pillar, Tongue and Buccal Surface, with Treatment and apparent Cure," was read by Dr. S. A. Oren, of Lanark, Ill. The papers by Drs. Jackson, Roy and Oren were discussed by Drs. O. T. Freer, of Chicago; John N. Mackenzie, Baltimore; C. N. Cobb, of Lynn, Mass.; J. Holinger, of Chicago, and Jackson, Roy and Oren, in closing.

"The Changes in the Facial Bones due to Adenoids" was read by Dr. A. T. Mitchell, of Vicksburg, Miss.

"A modified Leiter apparatus for the ear" was exhibited by Dr. Emil Amberg, of Detroit.

Thursday, June 6—Morning Session.

The members convened at 9:30 a. m.

"The Diagnosis and Treatment of Mastoiditis" was read by Dr. E. B. Dench, of New York City, and discussed by Drs. J. Holinger, of Chicago; Redmond Payne, of San Francisco; Emil Amberg, of Detroit; S. A. Oren, of Lanark, Ill.; Hiram Woods, Jr., of Baltimore; Sherman, of Cleveland; C. M. Cobb, of Lynn, Mass.; J. F. Barnhill, of Indianapolis; A. E. Prince, of Springfield; Camden, of Detroit; C. H. Baker, of Bay City; D. A. Kuyk, of Richmond; Robert Levy, of Denver; Brownell, of New York, and Dench, in closing.

"Mastoiditis after Subsidence and without Recurrence of Tympanic Disease," was read by Dr. Hiram Woods, Jr., of Baltimore, and discussed by Drs. E. B. Dench, of New York City; H. Harlan, of Baltimore; Emil Amberg, of Detroit; George C. Stout, of Philadelphia; Cornelius Williams, of St. Paul, and Woods, in closing.

On motion by Dr. D. A. Kuyk, of Richmond, Va., the Secretary of the Section was instructed to send out requests for laryngologic and otologic specimens for the pathologic exhibit at the next meeting.

Thursday, June 6—Afternoon Session.

The members convened at 2:30 p. m.

"Report of Case of Unusual and Interesting Tertiary Manifestations" was read by Dr. G. Hudson Makuen, of Philadelphia, and discussed by Drs. W. E. Casselberry, of Chicago; G. C. Stout, of Philadelphia, and Makuen, in closing.

A microscopic specimen was presented by Dr. J. Holinger, of Chicago, illustrating spongifying of the capsule of the labyrinth (sclerosis). It was discussed by Dr. C. M. Cobb, of Lynn, Mass.

The Section then adjourned *sine die.*

Section on Materia Medica, Pharmacy and Therapeutics.

Tuesday, June 4—Afternoon Session.

Chairman, Dr. N. S. Davis, Jr., called Section to order at 2 p. m

In the absence of Dr. J. M. Upshur, the Secretary, Frank Woodbury, of Philadelphia, was elected Secretary. Dr. A. B. Lyons offered motion of sympathy to Dr. Upshur in his illness, which was carried.

The Chairman appointed Drs. Hallberg, G. F. Butler and Jas. G. Kiernan to represent the Section in General Executive Committee.

Dr. W. Byron Coakley, of Chicago, read a paper on "Experimental Work in Intra-organic and Venous Injections and Blood Extracts in the Cure of Acute Organic Diseases." Dr. O. T. Osborne, New Haven, read a paper on "Therapeutic Indications Presented by the Conditions of the Blood in Disease." Discussion of both papers combined, by Coakley and Osborne.

Dr. John H. Musser, of Philadelphia, made a communication on "Chronic Myocarditis." Discussion by Drs. Henry Beates, S. E. Solly, O. F. Osborne, W. W. Tompkins, and Musser.

Dr. Heinrich Stern, New York, read a paper on "Treatment of Obesity."

Dr. Harold N. Moyer read a paper on "Treatment of Neurasthenia." Discussion by Drs. Shelly, Stern, Putney and Moyer.

On motion, the Chair appointed Nominating Committee: A. B. Lyons, of Detroit; O. T. Osborne, of New Haven; J. M. Dodson, of Chicago.

Wednesday, June 5—Morning Session.

Dr. F. T. Wahrer, of Fort Madison, read a paper on "A Plea for More Uniformity and Strength in Our Armamentarium." Dr. A. B. Lyons, of Detroit, read a paper on "Standardization of Crude Drugs and Galenical Preparations." Discussion by Drs. Hallberg, Walling, Wilson, Dickerson, and the Chairman.

The Chair read a communication from the American Pharmaceutical Association, announcing names of Delegates to this Section: F. J. Walling, E. Floyd Allen, Wm. A. Frost, Charles T. Hiller, Saul F. Boyce, A. B. Prescott, E. M. Houghton, F. E Stewart, S. E. Jelliffe, H. K. Mulford, H. R. Slack, C. H. G. Kile, F. S. Hereth, W. M. Sempill, G. M Beninger, C. S. N. Hallberg. On motion these delegates were invited to take part in the discussion and become members of Section for this meeting.

Wednesday, June 5—Afternoon Session.

Dr. S. E. Solly, of Colorado Springs, made a communication entitled "Indication for and Utility of Altitude Treatment of Pulmonary Tuberculosis." Dr. Norman Bridge, Los Angeles, read a paper on "Adaptability of Southern California and Similar Climates to the Needs of Consumptives." Dr. A. Burroughs, Asheville, read report on "Nineteen Years' Experience with Creosote in Tuberculosis." Dr. Arnold C. Klebs, Chicago, read a paper on "Specific Therapeutics in Pulmonary Tuberculosis." Dr. Norman Bridge read a paper on "Proper Management of the Tuberculous Lung." Discussion by Drs. Rochester, Bonney, Miner, More, Solly, Bridge and Hallberg.

Dr. DeLancey Rochester, of Buffalo, read a paper on "Treatment of Lobar Pneumonia." Dr. L. Dickerson, of St. Louis, on "The Abortion Treatment of Pneumonia; a Plea for the Use of Cardiac Depressants in the Treatment of the Congestion Stage of Pneumonia." Discussion by Drs. Rochester, Dickinson, Spilman, More, Caston, McCoy, Hawkins, and Chairman.

The report of the Nominating Committee was presented, naming Drs. G. F. Butler, of Alma, Mich., for Chairman, and Dr. C. N. Hallberg, of Chicago, for Secretary. On motion the report was adopted and candidates unanimously elected.

Thursday, June 6—Morning Session.

Dr. Boardman Reed, of Philadelphia, read a paper on "Influence of Certain Common Remedies upon Gastric Functions." Dr. Gustav Fuetterer, of Chicago, read a paper on "Treatment of Gastric Ulcer." Dr. Charles G. Stockton, of Buffalo, read a paper on "Treatment of Gastric Hyperesthesia." Discussion by Drs. Herrick, Tompkins, Fuetterer, Osborne, Johnson, Stern, McCoy, Westbrook, McCrae, Reed, and Stockton.

Thursday, June 6—Afternoon Session.

On motion the Chairman was authorized to name the two representatives of this Section in the House of Delegates. The following members were appointed delegates from Section on Materia Medica, Pharmacy and Therapeutics: Drs. O. T. Osborne, of New Haven, and A. B. Lyons, of Detroit.

In the absence of the author, an abstract of a paper on "Theory and Practice of Organotherapy," by Dr. Solomon Solis-Cohen, of Philadelphia, was read by the Secretary. Dr. Sidney Kuh, of Chicago, read a paper on "Akromegaly Treated with Pituitary Body." Dr. John M. Dodson, Chicago, read the report of a case of "Treatment of Graves' Disease with Thymus Extract." Discussed by Drs. Osborne, Boardman Reed, Davis, Woodbury, Shelly, Vaughan, Stern, Kuh and Dodson.

Dr. E. F. Houghton, of Detroit, read a paper on "Pharmacology of the Suprarenal Gland and a Method of Assaying Its Products." Dr. Jokichi Takamine, of New York, read a paper on "The Active Principle of Suprarenal Glands." Discussed by Drs. Vaughan, Stern, Reed, Dodson, Houghton and Takamine.

A communication from the Business Committee was presented by Drs. Billings and Bridge relative to consolidating the Section. Dr. Osborne moved that this Section be divided and the part of Therapeutics and Pharmacy be transferred to the Section on Practice, and the Materia Medica be consolidated with Physiology and Pathology. On motion the Chairman appointed a committee consisting of Drs. Osborne and Lyons, to confer with the members of the Section on Physiology and Pathology to determine upon the officers of the combined Sections for the next meeting.

A vote of thanks was passed to the officers of the Section for the efficient and faithful performance of their duties.

The Section adjourned *sine dic.*

Section on Physiology and Dietetics.

First Day—June 4.

The meeting was called to order by Dr. W. S. Hall, of Chicago, in the absence of the Chairman.

Two vacancies in the Executive Committee were filled by the appointment of Dr. Charles Hazen, of Virginia, to fill the unexpired term of Dr. Randall Hunt, of Shreveport, La.; and of Dr. R. Harvey Cook, of Ohio, to take the place of Dr. James Weir, Jr., of Owensboro, Ky.

Communications were received from the General Executive Committee of the Association to meet with the Committee on Reorganization at 3 p. m.; and to meet the General Executive Committee each day at 5 p. m. for the general business of the Association.

The advisability of a fusion with the Section on Pathology and Bacteriology was considered and the Executive Committee directed to confer with the Executive Committee of the Section on Pathology and Bacteriology with this end in view for 1902.

Owing to the absence of two members on the program for papers, a motion to combine the programs of June 4 and 5 was carried, and the Section dismissed to meet at 2 p. m., June 5.

Second Day—June 5.

Section was called to order, in the absence of the Chairman, by Dr. Winfield S. Hall, of Chicago.

Dr. Hall moved that owing to the impossibility of Dr. Lee attending the meeting, Dr. Charles M. Hazen be elected Chairman for the balance of the St. Paul meeting. The motion was carried.

Dr. Hall reported that pursuant to the action of the previous day, the Executive Committee of the Section had met the Executive Committee of the Section on Pathology and Bacteriology in the interest of fusing the two Sections; and that the two committees were very easily brought to a common understanding as to how this fusion should be brought about. The members of these two committees being members of the General Executive Committee, yesterday recommended that the fusion be made, to take effect in 1902. The Section on Pathology and Bacteriology is to grant to the Section on Physiology and Dietetics one member from that Section on the Executive Committee. They accord to the physiologists the Chairman every third year; and to the pathologists and pharmacologists the other two years.

It was moved that the Chairman and Secretary represent the Section on Physiology and Dietetics in conference with the Nominating Committee of the Section on Pathology and Bacteriology to see that the physiologists shall be represented in their Executive Committee, and in the offices of the new amalgamated Section. Carried.

Dr. Hall reported that it had been proposed to him to include also in this fusion the pharmacologists so that the whole field of experimental medicine might be grouped in one section.

Dr. Winfield S. Hall read a paper on "The Evaluation of Anthropometric Data," and was discussed by Drs. John Madden, of Milwaukee, and H. S. Drayton, of New York City. Dr. Hall closed the discussion.

Dr. John Madden, of Milwaukee, read a paper on "The Education of the Degenerate—A Physicobiologic Study." It was discussed by Drs. Winfield S. Hall, of Chicago; H. S. Drayton, of New York City; James Putney, of Charleston, and John Madden, in closing.

Dr. H. S. Drayton, of New York City, read a paper on "The Nervous Relation in Diseases of the Nutritive System." It was discussed by Drs. W. S. Hall, of Chicago, and H. S. Drayton, in closing.

A paper entitled "Isolation of the Active Principles of the Suprarenal Gland—A Review of the Work," by Dr. T. B. Aldrich, of Detroit; was read by Dr. E. M. Houghton, of Detroit.

On motion, Dr. L. Duncan Bulkley, of New York City, and Dr. R. Harvey Cook, of Oxford, Ohio, were elected to represent the Section on Physiology and Dietetics in the House of Delegates, and Dr. John Madden, of Milwaukee, as alternate.

Third Day—June 6.

Dr. D. E. Salmon, of Washington, D. C., read a paper on "Food Products from Diseased Animals." It was discussed by Drs. Chas. M. Hazen, of Richmond, Va.; Winfield S. Hall, of Chicago; David Paulson, of Chicago; R. Harvey Cook, of Oxford, Ohio, and Salmon, in closing.

A paper, "Living on Bread," by Dr. Alexander Haig, London, Eng., was read by the Secretary, and discussed by Drs. Winfield S. Hall, of Chicago; David Paulson, of Chicago, and R. O. Beard, of Minneapolis.

The Secretary was directed to write a note of thanks to Dr. Haig for his paper.

"The Teaching of Practical Dietetics in Medical Schools" was read by Dr. R. O. Beard, of Minneapolis, and discussed by Drs. Winfield S. Hall, of Chicago; Stewart, of Michigan, and C. M. Hazen, of Richmond, and Dr. R. O. Beard, in closing.

A paper on "Ponto-Bulbar Heat Center," by Dr. Edward T. Reichert, of Philadelphia, was read by the Secretary, and discussed by Dr. Beard, of Minneapolis.

The Section adjourned *sine dic.*

Section on Pathology and Bacteriology.

Tuesday, June 4—Afternoon Session.

The Section was called to order by the Chairman.

Address by the Chairman, Ludvig Hektoen, of Chicago.

The following papers were read: "Effect of Direct, Alternating and Tesla Currents and X-rays on Bacteria," by F. Robert Zeit, of Chicago: "Demonstration of Specimens, Slides and Photomicrographs of Uretero-intestinal Anastomosis," by F. Robert Zeit, of Chicago; "Demonstration of the Van Gehuchten-Nelis Histologic Reaction for Hydrophobia and Remarks on Hydrophobia in Ohio," by A. P. Ohlmacher, of Gallipolis, Ohio; "Carcinoma of the Lung," by E. R. Le Count, of Chicago; "The Influence of Structure and Locality on Pathological Processes," by J. S. Foote, of Omaha, Neb.

It was moved by Dr. Stengel, duly seconded, that the Chairman appoint a Nominating Committee. Carried.

The Chair appointed as such Committee Drs. W. A. Evans, Frank B. Wynn, and Joseph McFarland.

It was moved by Dr. Stengel, duly seconded, that the matter of consolidating the Sections on Pathology and Bacteriology and Physiology and Dietetics be referred to the Executive Committee, with the recommendation of favorable action thereon. Carried.

On motion of Dr. Wells, duly seconded, Dr. Ohlmacher was made a member of the Executive Committee, vice Dr. W. G. Spiller, absent.

Wednesday, June 5—Morning Session.

Section called to order by the Chairman.

The following papers were read: "The Endothelial Cells in Acute and Chronic Infections," by E. R. Le Count, of Chicago; "The Mast Cells in Acute and Chronic Infections," by Herbert U. Williams, of Buffalo (by invitation). The papers were discussed by Drs. Wells, of Chicago, and H. D. Vallens, of St. Peter. "Some Studies of Venoms and Antivenin" was read by Joseph McFarland, of Philadelphia.

Wednesday, June 5—Afternoon Session

Section called to order by the Chairman.

The Nominating Committee submitted the following report, and, on motion of Dr. Herzog, the same was adopted: Chairman, Frank B. Wynn, of Indianapolis; Secretary, W. T. Howard, of Cleveland. For Executive Committee: Terms to expire in 1902, A. Stengel, of Philadelphia; term to expire in 1903, W. S. Hall, of Chicago; term to expire in 1904, Ludvig Hektoen, of Chicago.

On motion of Dr. W. T. Howard, duly seconded, the General Executive Committee of the Association was urged to recommend to appropriate $500 to cover the expenses of a pathological exhibit at the meeting of 1902.

"Primary Sarcoma of the Esophagus and Stomach," was read by W. T. Howard, Cleveland, and discussed by Dr. Le Count, and, in closing, by Dr. Howard.

"A Study of a Fetal Stomach, with Special Reference to the Origin of Acid-Secreting Cells," by W. A. Evans and William Becker, Chicago.

"Report of a Case of Primary Carcinoma of the Appendix, and a Case of Lymphosarcoma of the Intestine, with a Discussion of the Etiology of the Latter," by S. M. White, Minneapolis.

"Isolation of Bacillus Typhosus from Unusual and Interesting Localization," by O. M. McDaniel, Minneapolis. Discussion was by Drs. Herzog and Westbrook.

"Notes on the Bacteriology and Morbid Histology of Cerebrospinal Meningitis," was read by L. B. Wilson, Minneapolis, and discussed by Dr. Hall.

"On the Growth of Epithelium," was read by Leo Loeb, Chicago, and discussed by Dr. Le Count.

Thursday, June 6—Morning Session.

Section called to order by Dr. Howard, in the absence of the Chairman.

Secretary-elect Howard presented his resignation as Secretary for the ensuing year, and, on motion of Dr. Stengel, the resignation was accepted.

On motion of Dr. Stengel, Dr. Joseph McFarland, of Philadelphia, was elected Secretary for the ensuing year.

The Secretary presented a bill of $184.45 for carpenter work, etc., in the pathological exhibit, and on motion of Dr. Stengel, duly seconded, the bill was referred to the Local Committee, with a demurrer as to the amount thereof.

"On the Nature and Significance of Granular Degeneration of Red Corpuscles," by Alfred Stengel, Philadelphia.

"Study of an Epidemic Among Guinea Pigs in the Laboratory," by Victor C. Vaughan, Ann Arbor, Mich.

"The Influence of Boric Acid and Borax on Milk Bacteria," by Wm. H. Veenboor, Ann Arbor, Mich.

"The Influence of Formaldehyde on Milk Bacteria," by Victor C. Vaughan, Ann Arbor, Mich.

Specimens of annular pancreas were exhibited by Dr. Edward F. Wells, of Chicago, for Dr. Theo. Tieken.

On motion of Dr. McFarland, duly seconded, the following members were elected as delegates to the House of Delegates: For one year, Dr. Alfred Stengel, Philadelphia, and for two yars, Dr. Wm. A. Evans, Chicago.

On motion of Dr. Ohlmacher, Dr. Charles Hazen, of Richmond, Va., was duly elected Treasurer of the Section.

On motion of Dr. Wynn, Physiology and Pathology was adopted as the title of the consolidated Sections.

The Section adjourned *sine die.*

List of Association Members Registered in the Different Sections at St. Paul, June 4-7, 1901.

The total registration at the St. Paul meeting was 1806.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Puerperal Eclampsia.

R. P. R. Lyle, of the University of Durham, in an article in the *New York Lancet*, gives three great principles to be observed in the treatment of eclampsia: 1, the purifying of the blood; 2. to control convulsions; and 3, the emptying of the uterus. The first is to be accomplished by promoting diuresis, producing purgation and diaphoresis. To meet the second principle it is necessary to allay irritability of the cerebrospinal system. Morphin in his opinion has the following advantages over other cerebrospinal depressants: 1. It controls the convulsions by allaying cerebrospinal irritability. 2. It prevents the excess of waste products from being thrown into the blood. 3. It does not weaken the patient. 4. It does not injure the child. 5. It has no effect on the kidney. 6. When the patient is under its influence labor often commences, and quickly terminates without causing more convulsions.

Dionin in Disease of the Cornea.

Dr. L. Vernies, in *Klin. Ther. Woch.*, states that he uses dionin in all corneal diseases and those of the iris and ciliary body, where it is best applied in combination with mydriatics. He uses it in solution of 5 to 10 per cent. strength. Ulcers of the cornea heal rapidly under its influence. It acts especially by increasing the flow of the lymph.

Treatment of Gout.

In painful finger joints due to chronic gout, the following is recommended by Dr. Solis Cohen:

℞.	Olei gaultheriæ			
	Guaiacoli, āā	m. xx	1	33
	Camphoræ			
	Menthol, āā	gr. xv	1	
	Ol. caryophylli	m. v.		33
	Glycerini			
	Petrolati			
	Lani, āā	ʒi	4	

M. Sig.: Apply locally and rub in thoroughly.

He states that much larger quantities of the active ingredients, even up to saturation, may be used.

As a Tonic and Eliminant in Infectious Diseases of Children.

℞.	Ferri et ammon. citratis	℥ss	16
	Tinct. nucis vom.	ʒss	2
	Sol. potass. arsenitis	ʒss	2
	Tinct. calumbæ	℥ss	16
	Syr. limonis	℥i	32
	Aquæ, q. s. ad	℥iv	128

M. Sig.: One teaspoonful in water after each meal.

Glonoin in Angina Pectoris.

H. E. Lewis, in *Merck's Archives*, recommends glonoin in spasmodic contraction of muscular tissue. In angina pectoris it is recommended as follows:

℞.	Spts. glonoini		
	Spts. chloroformi, āā	ʒss	2
	Tinct. capsici	ʒi	4
	Aq. menth. pip. q. s. ad	℥i	32

M. Sig.: A teaspoonful every four hours, with a repetition of the dose immediately at the onset of the attack.

Murrel advises that the solutions of glonoin be warmed at least to the temperature of the body as it is thus more readily absorbed.

Hyperemesis of Pregnancy.

J. W. McLane, in *Med. News*, recommends complete rest in bed; have all the food given by the nurse, and keep the patient's mind away from the stomach. He recommends as a diet, peptonized milk, beef tea, preferably unsalted eggs, and raw oysters. An enema containing a few drops of tincture of opium, and one teaspoonful of brandy is good. Examine the uterus and if it is anteverted or retroverted or bound down with adhesions, tampon with gauze impregnated with boric acid, vaselin and glycerin. If the vomiting can not be stopped anesthetize, scoop out the ovum with the finger, curette, douche and insert a gauze drain.

Sciatica.

In sciatica, neuralgic headache and intercostal neuralgia the following is recommended as a local application:

℞.	Olei gaultheriæ			
	Guaiacol, āā	m. xv	1	
	Menthol	gr. x		66
	Lanolini	ʒii	8	

M. Place in a tin tube. Sig.: A small quantity about the size of a pea to be well rubbed in over seat of pain, night and morning.

Drugs in Heart Disease.

H. A. Hare, in *Ther. Gazette*, praises very highly the value of digitalis and massa hydrargyri in certain forms of heart disease. When the heart becomes incompetent as evidenced by enlargement and tenderness of the liver, the hepatic circulation is necessarily retarded. The administration of massa hydrargyri relieves this congestion and increases the activity of the liver. Hare states that it is probable that the relief of liver engorgement is accompanied by an increased ability to destroy toxic material in the circulation or in the elimination through the bile. It is also known that mercury increases renal elimination, consequently the stasis in the portal circulation is relieved, which in turn lessens the work thrown upon the heart. In some cases, he states, digitalis fails to produce proper results till mercury in this form is freely given.

To Remove Freckles. (Lentigo).

The following lotion is recommended by *Pratico del Med.*

℞.	Hydrarg. chlorid, corros.	gr. xv	1
	Zinci sulphatis	gr. xxx	2
	Aq. plumbi	ʒss	2
	Aq. rosæ	℥viii	256

M. Sig.: Apply locally night and morning.

Treatment of Warts.

The following has been recommended, in the removal of warts, by the *New York Lancet*:

℞.	Hydrarg. chloridi corros.	gr. v		30
	Acidi salicylici	ʒi	4	
	Collodion q. s. ad	℥i	32	

M. Sig.: Paint the application over the warts once a day. After a few applications the warts peel off.

Carcinoma of the Skin.

Unna, as noted in the *Post-Graduate*, places the Paquelin cautery in first rank as a therapeutic agent. This is generally used superficially, singeing the parts only. He states that he has observed a checking of the malignant process and the appearance of granulation tissue. He regards resorcin as second in efficiency used in an alcoholic solution of 5 per cent. strength, or in the form of a plaster. Resorcin seems to be more effective when combined with benzoic acid in same strength solution. He also recommends the following to be applied in the form of a plaster:

℞.	Acidi arsenosi		
	Ext. cannabis indicæ, āā	gr. lxxv	5
	Acidi salicylici	ʒv	20

M. *prepare on plaster mull.*

He states that under the use of this application, cancerous tissue breaks down, while the healthy skin will resist for a much longer period.

Asphyxia by Drowning.

E. H. Bayley, in *Northwestern Lancet*, emphasizes the following points, stating that the success of the treatment depends upon immediate action: 1. The patient should not be carried all around town before trying to resuscitate him. 2. The body should be inverted and the head and face should be kept down so that the tongue will fall forward, permitting the water to escape from the mouth. 3. The patient should be taken to the nearest house, the clothing is to be removed, and warmth is to be applied with hot, woolen blankets, and one is to keep at work until bodily heat is fully restored. Assistants should rub the body while the blankets are being changed. 4. Artificial respiration should be begun with head down and hips elevated. 5. Stimulants—as strychnin sulphate, aromatic spirits of ammonia and coffee—are to be given. 6. When respiration and circulation have commenced, one should lay the patient on his back, occasionally *rolling* him from one side to the other to lessen the danger of local congestions.

Medicolegal.

City Not Liable for Negligence of Hospital Surgeon.—The Indianapolis City Hospital is maintained and operated under a statute which provides that the department of health and charities shall be under the control of three commissioners who shall be practicing physicians, who, among other things, shall have charge of the city hospital, and are authorized and directed to prepare ordinances for the efficient regulation and management of such hospital, as may seem to them desirable. In the case of Williams vs. the City of Indianapolis, the latter was sued for damages alleged to have been sustained through the negligent and unskilful treatment given a non-paying patient with a broken arm by an alleged incompetent and unskilful physician and surgeon negligently employed in the city hospital. The Appellate Court of Indiana, however, holds that there was no liability on the part of the city. It holds that the duty imposed on the board of commissioners by the statute is governmental. The board, it says, acts for the public, not as the agent of the municipality in its corporate character. Considerable reliance, the court goes on to state, was placed on a Rhode Island decision in an action that was brought by a paying patient against a hospital administered largely as a charity, where the court seems to have treated the hospital as any other corporation. But in this case the patient being averred to have been a non-paying one and the hospital being operated by the municipality, the court holds that its exemption from liability for damages rests upon broader grounds than that of a private institution operated as a charity. It also suggests that the true doctrine, upon facts parallel with those before the Rhode Island court, is that "the damages should be paid out of the pocket of the wrongdoer, and not from the trust fund."

Commenting on Failure to Make Physician Witness.—The Supreme Court of Indiana holds, in the case of Brackney vs. Fogle, that the rule that it is proper for counsel to comment upon the failure to call accessible witnesses who know, or are supposed to know, about the facts in controversy, does not apply to the failure to call a privileged witness. This was a suit to contest a will upon the ground of mental unsoundness and undue influence. During his argument to the jury, an attorney for the contestants was permitted to comment on the exclusion as a witness, upon the objection of the administrator, of the physician who had attended the testatrix in her last illness, and he commented on the right of the administrator to waive the statute, and permit the physician to testify, and to call him as a witness. Among many other things, the attorney said, in effect, that the doctor had been with the testatrix shortly before the will was executed, knew her condition, could and would have told it, and that the witness was kept from the stand to suppress the truth. The judge, who allowed this, instructed the jury that, under the law, the administrator had the legal right to object to the physician's testifying to any facts that came to his knowledge while professionally treating the testatrix, such matters being confidential; but the administrator had the right to waive objection to such testimony, and could himself call the doctor to the stand, and his failure to do so, or permit him to testify to such facts, might rightfully be commented on by counsel, and that the jury might consider the conduct of the administrator in these respects, with all the other evidence, in determining the case. The Supreme Court holds that this was reversible error.

Damages for Loss of Arm after Amputation of Fingers.—The case of Rich vs. Moore was brought to recover damages from a physician for the loss of an arm which it was alleged that, on account of his negligence, had to be amputated above the elbow some 18 days after an injury to the hand which was so severe that it was necessary to amputate the fingers, which the defendant and another physician called by him did, after which he treated the case for 5 or 6 days, when he surrendered it, refusing to consult or act with another physician then called in. Further facts are not given. But there was a verdict and judgment for the plaintiff. This latter, however, the Supreme Court of Iowa reverses for the inadvertent use of the word "plaintiff" instead of "defendant" in the clause beginning with "but" in the following part of an instruction to the jury: "To render the defendant liable, there must not only have been negligence on his part in some manner as charged, without contributory negligence of plaintiff or others caring for him, but such negligence of plaintiff, if shown, must have been the proximate cause of the injury." As the instruction read, the court says that it was erroneous, as, under the well-settled doctrine, any negligence of the plaintiff contributing to the injury complained of would defeat his recovery of damages. Another point to which the defendant took exception was to the plaintiff being permitted to prove what he had earned, per year, before his arm was taken off, and what he had earned since. This was assigned as error, on the ground that an amputation of the fingers of the hand was conceded to have been necessary, and the difference in his earning capacity should have been confined to his condition after his fingers were removed, instead of as a sound man. This objection the court, however, does not think well taken. It says that it is not always possible to produce evidence which shall meet exact conditions. The man was a farmer and farm hand. Whether he might have produced evidence tending to show what a man with the fingers of one hand gone might have earned at that work, the court does not know; but men so afflicted are not common, and the court is satisfied with the result in this respect as it thinks the verdict returned showed that the jury gave due consideration to this difference in physical perfection, although it does not state what was the amount of the verdict.

Criminal Abortion: Its Seriousness, Proof, Punishment.—The Supreme Court of Idaho says, in the case of State vs. Alcorn, that an unnatural abortion, brought about by means of drugs or instruments, violates decency, the best interests of society, the divine law, the law of nature, the criminal statutes of that state, and is not only destructive of a life unborn, but places in jeopardy the life of a human being,—the pregnant woman. Both actors, when there are two, are guilty of felony, and ought to be punished by the law, if the woman survives; and, if she does not, then the person or persons participating in the abortion should be punished. This crime is one of grave consequences to society. The law prohibits it and prescribes severe penalties. The law ought to be strictly enforced. Furthermore, in a case of this kind, the court says that it will not notice purely technical errors, which do not prejudice the substantial rights of the accused, for the purpose of reversing the verdict returned by the jury, especially where it is satisfied that substantial justice has been done. Under the statutes of Idaho, the crime of abortion may be committed prior to the quickening of the fetus, but the rule is otherwise at the common law. Then, the corpus delicti, or substance of the offense, the court holds, may be proven by declarations and circumstances, but the order in which the evidence proving the different material facts is introduced is not material. In a prosecution upon the charge of murder, where the death of the deceased is alleged to have resulted from an operation performed for the purpose of bringing about an abortion, the pregnancy of the deceased must be proven beyond reasonable doubt, but need not be demonstrated to an absolute certainty. In case of homicide resulting from an operation performed by the accused upon the body of the deceased to bring about an abortion, the declaration of the deceased, made at the time she was introduced to the accused, to the effect that she was pregnant, and which had direct reference to the contemplated transaction between the deceased and the accused, the court holds, is admissible in evidence as a part of the res gestæ, or essential circumstances of the transaction. It also holds that where an unnatural abortion is sought to be caused by the use of instruments and drugs, or either, and death results, an abortion not being necessary to save the life of the woman, such acts, under the statutes of Idaho, constitute the crime of murder in the second degree; and an instruction that such acts constitute the crime of murder in the second degree or manslaughter is erroneous.

Sufficient Evidence of Malpractice to go to Jury.—In the case of Degelau vs. Wight, brought against two physicians practicing in partnership to recover damages for the death of a woman which was alleged to have been caused by their negligent and unskilful treatment, the Supreme Court of Iowa has reversed a judgment entered in their favor on a directed verdict. The woman, who was 21 years of age when she died, had nearly seven months before that given birth to a child, and, although she was up again in a week or two, had thereafter been troubled with intermittent pains, finally consulted the defendants, and, on their advice, submitted to the operation of curettage of the uterus. As one witness put it, they said her trouble "was something of the afterbirth of the child." About an hour and a half was consumed in performing the operation, both physicians leaving about half an hour later and before the patient had recovered consciousness, or at about 11 a. m. During the day she became worse, suffered severe pain, and died at 10 o'clock in the evening. There was evidence tending to show that it was not probable that any part of the afterbirth could have remained in the womb so long, and also evidence from which a jury might have been justified in drawing the inference that no necessity existed for the operation of curettage. At a post-mortem examination the uterus was removed, and it was found to be torn to the extent of an inch or an inch and a half, so that the handle of a scalpel was passed through the hole. The membrane also gave evidence of having been scraped, there being three deep furrows about an eighth of an inch apart. The condition described was said to be sufficient to cause death, either directly or from the resulting shock. It was also shown that a tear like that made in curetting the uterus could have been discovered by the operator, and that a proper course, on its being known, would either be to sew it up, or give medicine to sustain the patient until the shock was over, and then permit nature to repair the wound. The foregoing was the evidence most favorable to the plaintiff, and without wishing to be understood as expressing an opinion as to its weight, nor as suggesting the conclusion that a jury should deduce from it, the Supreme Court holds that it made a case upon which a jury should pass, and that it was error to take the case from the jury, the question of negligence being one of law only when from the facts all reasonable men must draw the same conclusion. That none but the organs in the abdominal cavity were inspected at the autopsy, and none of the physicians examined as witnesses attempted to say that no other cause of death existed, the court holds, affected only the weight of their testimony.

AMERICAN.

1. **Syphilitic Fever.**—After reporting three cases illustrating various points in regard to the condition, Futcher sums up the following as to be emphasized in this connection: 1. In all cases of fever of obscure origin the possibility of it being syphilitic should be borne in mind. 2. Experience has shown that physicians of reputation, as well as those of limited experience, are prone to mistake the condition for one of the acute specific fevers. 3. The affections for which syphilitic fever is most often mistaken are malaria, typhoid fever, tuberculosis, sepsis, and occasionally rheumatic fever. 4. The fever may occur as early as four weeks previous to the appearance of the secondary skin eruption, or, what is of greater importance, late in the disease after tertiary manifestations have existed probably for years. 5. The fever may be continuous, remittent, or intermittent. The remittent type is regarded as the most frequent form in the fever of invasion. The fever is often associated with chills and sweating. 6. Careful examinations of the long bones and viscera for evidences of tertiary lues should be made in all cases of fever of obscure origin.

2. **The Ophthalmoscope.**—The history of the ophthalmoscope is given very thoroughly by Theobald; he gives full credit to Babbage, who is not usually recognized by medical writers as the originator of the ophthalmoscope. He says that while Helmholtz deserves a certain amount of credit, that which was essential in his ophthalmoscope was not wholly original, and that which was original was not only distinctly not essential, but was the outcome of a misconception—a fortunate misconception as it turned out—upon his part. Within a few months of the announcement, the method of illuminating the eye which he suggested was to a great extent put aside for that of the ill-starred Mr. Babbage. Other names connected with the early history of the ophthalmoscope are mentioned, such as Spencer Wells, etc. The importance to ophthalmology of the instrument, he thinks, is best illustrated by a comparison

to a ship without a rudder, compass and sextant, and not only ophthalmology but neurology and other departments of medicine are benefited by it.

4. **Malarial Buboes.**—Smith reports five cases of inguinal buboes as complications of malarial fever, giving temperature charts and daily records. He has observed other cases and calls attention to the phenomenon as a matter of much importance and occurring without the suspicion of venereal infection and clearly dependent upon the fever. In conclusion he remarks on the reported existence in Cebu, P. I., of many cases of mild fever with glandular enlargement, and suggests that it will be interesting to know what these cases prove to be on investigation.

5. **Psychic Epilepsy.**—Courtney gives a description of the phenomena of psychic epileptic attacks and concludes that psychoses of epilepsy have very definite and immediate associations with other and irrefragible manifestations of the disease, that the plea of irresponsibility for criminal acts alleged to have been committed while the individual was suffering from epilepsy should be considered invalid unless other manifestations can be adduced, and that vague and ill-defined convulsions which date back to infancy do not constitute such other manifestations. He reports a case at some length as illustrating the intellectual petit mal. It was traumatic in its origin and presented the features of the "absences" of consciousness, amnesia and automatic acts.

6. **Medical Expert Evidence.**—The special case of the Bellevue Hospital attendant who was tried for murder of a patient and the differences of medical opinion adduced in the trial form the text of Pritchard's article. The charges made against the medical expert testimony generally he thinks are harsh and he criticizes certain points in the management of the case by the prosecution. He says medical expert testimony is more often defective from the manner of its presentation than from an assumed yielding of expert witnesses to whatever opinion is desired of him. Medical expert testimony has the indifferent witness who makes the possibilities of medical science his excuse for almost any opinion and such should be branded by the medical profession as cankers eating into their professional body. This last class of medical expert evidence is not found, however, in a trial of great public interest where the medical witnesses are the foremost members of the medical profession.

7. See abstract in The Journal, xxxv, p. 1048.

8. **Typhoid Fever.**—Hare and Landis conclude their article, reviewing the respiratory complications, the temperature in the well-developed stage, the skin lesions, eruptions, genitourinary symptoms in the developed disease and the symptoms on the side of nervous system and alimentary canal. Typhoid without intestinal lesions is mentioned, as are also the circulatory and blood changes.

9. **Hernia of the Bladder.**—Cheesman commences his paper with a report of cases, then passes to the history of the condition, its anatomical conditions, etiology and treatment. He concludes his paper with the following conclusions: 1. That the principal cause of bladder hernia is direct traction exercised through the peritoneal coat by the weight of the hernial mass, or by pull on the sac during ligation in operations for radical cure. 2. In one-sixth of the cases symptoms occur sufficient to arouse suspicion, sometimes amounting to certainty, of the existence of the abnormality. 3. In about one-fourth of the cases it may be possible during operation to recognize the bladder and avoid injuring it; and after one hernial sac has been found, any structure resembling a second should be regarded as bladder, till proved otherwise. 4. When the bladder is wounded, the best procedure is immediate suture by two layers of catgut, and closure of the hernial wound by Bassini's method; a small drain only being left leading to the bladder suture line. The bladder wall, when thinned, may be freely resected preparatory to closure. The catheter *à demeure* is not essential to primary union of wounds thus closed. 5. Urinary fistula nearly always closes spontaneously. 6. Injuries of the bladder have been directly responsible for death in only 10 per cent. of the hernia cases in which they occurred.

10. **The Nauheim Treatment.**—Heineman is a strong advocate of the Nauheim treatment, which he finds beneficial in a very large proportion of cases. He describes the methods and the dietary advised, and gives results. He thinks it is indicated in rheumatism, gout, inflammatory exudates, functional and incipient organic spinal disorders, spinal congestion, neurasthenia and early stage of locomotor ataxia, chorea, sciatica, and certain forms of neuritis; in circulatory disorders; in the conditions produced by chlorosis, hemophilia, and Barlow's disease, early arteriosclerosis, and aneurysm only in its incipiency; also in varicose condition of the veins; in all vasomotor disturbances. In cardiac diseases, it is indicated in myocarditis, fatty heart and all forms of loss of compensation, whether dependent upon muscular changes or valvular disease; also in angina pectoris and all forms of functional cardiac disorder. Its contraindications are Bright's disease, advanced aneurysm, and serious cases of advanced arteriosclerosis in which only with the utmost conservatism and watchfulness can good results be obtained and justify treatment. He cautions against too rapidly increasing the treatment, and remarks that in selecting the character of the bath and its temperature it should be kept clearly in mind that cool baths produce different physiologic effects from warm baths. Experience with every given case will have to be the guide to treatment.

11. **Nephrorrhaphy.**—The method here described by Sturmdorf and the case reported is the same as Edebohls' method as published in his article on movable kidney in the *American Journal of Obstetrics* in 1895, as far as incision and ablation of the tissue is concerned. After that the formation of the flaps is made in the following manner: "The kidney was pushed as near to the surface as possible, and steadied there by pressure exerted through the abdominal wall by the hand of an assistant. The capsula propria was incised longitudinally, exactly in the median line to within about three-fourths of an inch from either pole. A pair of closed curved, blunt-pointed scissors was introduced beneath this capsular incision, and the capsule was carefully separated from the kidney substance for an area corresponding to the longitudinal capsular incision in length and to the lateral borders of the kidney in width. The free capsule was now raised by mouse-tooth forceps; two flaps were formed with blunt-pointed scissors by slitting the capsule laterally at each end of the longitudinal incision, as shown in the diagram. The flaps were secured in the grasp of T-shaped forceps, while two silkworm retention sutures, equidistant from each other and from either pole of the kidney, were passed through skin, superficial fat, the tendons of the abdominal muscles, the cut and trimmed edges of the perirenal fatty capsule, the fibrous capsular flaps, and the parenchyma of the kidney, at a depth of about three-fourths of an inch from its surface, and left untied for the time being. The object of these sutures was not only to aid in relieving tension but to obliterate any possible hollow spaces, thus obviating the necessity for drainage, and at the same time securing firm coaptation of broader surfaces for subsequent cicatricial union. Longitudinal slits, corresponding in location and length to the position and width of the fibrous capsular flaps, were next made through the adjacent muscular tissue, and the flaps drawn through these slits were secured in place by a running suture of fine chromicized catgut. Three interrupted sutures of No. 3 chromicized gut were next passed so as to embrace muscle and kidney substance at a level with and equidistant from the above-mentioned silkworm sutures, and tied. The final suture included skin, superficial fat, and fascia, after which the silkworm sutures, originally left hanging loose, were drawn taut by means of shot and plate. Primary union occurred, the removal of the silkworm sutures being effected on the eighth day."

12. See abstract in The Journal of June 8, p. 1649.

14. **Moore-Corradi Method.**—The essential features of this method as stated in the article consist in: 1. A thorough exploration of the tumor by celiotomy, which permits a recognition of the approximate anatomic seat and relations and

furnishes valuable information as to its characteristics—an advantage not afforded in thoracic aneurysm. 2. The safe exposure and even permanent isolation of the point of attack in the most accessible part of the tumor by the formation of adhesions between the sac and abdominal wall, diminishing the shock and liability to perineal contamination. 3. The introduction at a second sitting after adhesions have formed and the sac becomes extraperitoneal of a highly drawn fine snarled silver wire, which should not exceed a No. 28 gauge (0.0085 inch) in diameter. Sterling silver will meet all the indications. 3. The wire should be fed or carried into the aneurysmal sac through a fine and carefully insulated trocar or cannula (shellac, celluloid, or rubber being used as the insulating agents, and the caliber of the canula not exceeding a No. 2 Dieulafoy aspirating needle). 5. The wire should be tested, first to determine the following points: That it will coil in large irregular loops so as to be distributed over the widest possible surface. That it will not form short continuous spirals with such spring and force as to cause injurious pressure on the aneurysmal walls, or, after finding its way into the aorta through a large orifice spring as it were, into the heart itself. It is important for the quantity of wire used to be adjusted to the size of the aneurysm so that retraction after coagulation may not be interfered with by its resistance. As a rule, 10 ft. will suffice for the average aneurysm, though larger quantities are advised in certain cases. 6. The electric current should be furnished by a galvanic battery with a positive pole attached to the wire, and the negative electrode well covered with a wet cloth, to the back. A milliampere meter should be connected with the circuit, to show the strength of the current, which should not exceed 70 milliamperes, for fear of caustic effects. The intensity of the current and the duration may vary within wide limits corresponding to the condition of the patient and the effect upon the tumor. In his case reported, the sitting was prolonged four hours and twenty minutes without appreciably bad effects after the sac had been rendered extraperitoneal. 7. The coincident administration of gelatin (3 per cent.) in decinormal saline solution (7 per cent. salt) in 6 or 8 ounce doses by hypodermoclysis, as suggested by Lancereaux, may be a useful adjuvant to rest, diet. and other general measures. The question whether this method is applicable to all forms or only special anatomical conditions is raised and Matas concludes that it is evident that there may be a comparatively small percentage of cases favorable and another much larger group not amenable to this procedure and where it is contraindicated.

15. **Traumatic Neuroses.**—Moyer concludes his paper by suggesting the following points for discussion: That concussion neurosis, in all its various appellations, is an unfortunate and misleading term; that clearer understanding of functional nervous troubles renders such a term unnecessary; that pain and tenderness of the spine is rarely an evidence of change in the cord, but is usually due to fatigue of the spinal muscles, or sprains and concussions of the column; that most of the symptoms of spinal concussion, as the term is commonly used, are cerebral in origin, and that a correct diagnosis and prognosis may usually be reached by analyzing all such cases after the same manner that we do functional nervous troubles having their origin in non-traumatic causes.

16. **Sympathetic Resection in Glaucoma.**—After mentioning the opinions *pro* and *contra* and methods of performing the operation. Mullen reports a case of excision of the sclerotic superior cervical ganglion for glaucoma. He puts it on record as agreeing with one reported by Panas in being followed by declining vision and, therefore, as showing that resection of the sympathetic in glaucoma does not always produce permanent curative results.

17. **Clinical Thermometers.**—Rosenberger has examined the clinical thermometer after ordinary cleansing, for bacterial contamination in various diseases, indigestion, gout, measles, scarlet fever, tuberculosis, diphtheria and bronchitis, and sums up his results in the following conclusions: 1. It is possible for the thermometer to be laden with the usual flora of the oral cavity. 2. Such bacteria may retain their capability of growth for an indefinite time, at least 2 months, as shown by the above experiments. 3. Many pathogenic bacteria possess similar capabilities, and it is not unreasonable to assume, although the above experiments are not conclusive upon this point, that transmission of bacterial disease by the thermometer is possible. 4. Thermometers are easily disinfected. 5. Where possible each patient should be possessed of a thermometer, as much his own property, and as sacred to his own use, as his toothbrush. 6. Where for reasons of economy or otherwise it is impossible to carry out the recommendations expressed in conclusion 5, the thermometer should be disinfected before and after using. 7. The custom now prevalent in the hospitals of keeping thermometers in disinfecting solutions is to be commended.

18. **Atypical Pneumonia and Phthisis.**—The importance of an early diagnosis in phthisis is considered, and the statistics as regards the antecedents of pneumonia in this disease discussed. Bergtold believes there are many cases occurring that are diagnosed pneumonia and recognized as tuberculosis only after the malady has declared itself beyond the aid of medicine. He emphasizes the point of being suspicious of any atypical pneumonia, not that he considers all such cases tuberculous, but believes that they are under suspicion. He thinks a more thorough examination of clinical histories and literature would show a larger percentage of atypical pneumonias previous to tuberculosis than is indicated by the data he has given.

19. **Electrolysis in Skin Diseases.**—Wisecup describes the methods employed by him for removal of superfluous hair and other conditions. On account of the variations of individual resistance he does not think the milliampere meter necessary, and advises the use of the smallest possible needle, not too sharp at the point; for the other electrode he allows the patient to hold his fingers in a cup of water, connected with the other pole. The rule he follows is to insert the needle about one-fourth inch into the average hair follicle, but a smaller distance for smaller hairs. Aim to have the needle come in contact with the hair bulb, which can be told by the slight resistance met. Leave the needle inserted until a white froth bubbles around it, but there is danger of leaving it too long and a scab or scar forming. Use preferably a straight needle, as small as possible, without a bulb. Among the diseases which he has treated are nevus, though the common birthmark is unsatisfactory under this head; also moles, cavernous nevus, dilated vessels, cicatricial scar tissue, xanthoma and blackheads.

20. **West Point Neurasthenia.**—Woodruff criticises the course followed at West Point as tending to exhaust the student and to produce neurasthenic conditions in after-service. He remarks that neurasthenia is recognized in the United States as a military disease. The work is three times as much as the human brain can do. The academy must abolish the unwholesome system of rejecting the cadets, who, though very able, are not possessed of an unwholesome and abnormal brightness and quickness. He thinks by retaining them and by shortening the course the academy could supply three times the number of efficient officers it now does. Congressmen could make appointments every two years without increase in the number of cadets.

23.—See abstract in THE JOURNAL of May 11, p. 1338.

26. **Jacksonian Epilepsy.**—In this conclusion of Putnam's article he points out that it is by no means certain that in Jacksonian fits there is a discharge beginning at the point corresponding to the signal symptom. The longer the time during which the seizures due to localized irritation occur, the more widely the brain as a whole becomes involved and the co-operative action of ever-widening areas of the brain may show itself almost from the outbreak. In this case the patient with traumatic or focal epilepsy probably differs but little, if at all, from patients of idiopathic epilepsy. The theory here advocated by Putnam is what he calls the "inhibition" and "formation of new habit" theory which he considers at present the best one available. He believes that the arrest of epilepsy through surgical operation is an affair primarily of inhibition, and next the establishment of a new habit, made possible by the

temporary arrest of the morbid outbreaks. He does not think it necessary to look to a focal lesion for this. The therapeutic problem is how best to secure this inhibitory action and he thinks that possibly as much good can be done by mere exposure of the brain as by incision, or perhaps more. Whatever the operation, in his opinion, it should be considered that the arrest of the symptoms is mainly useful as affording a better opportunity for bromid medication. This part should be taken up energetically. He does not consider it necessary to give the details of bromid treatment, but suggests that the Charcot method, recently recommended by Tourette, of increasing the dose for three weeks, and then dropping to the starting point, and so on, and reinforcing the treatment by every hygienic influence that can be devised, is probably as good as any method.

27. **Prostatic Hypertrophy.**—The conclusions which Horwitz deems himself justified in forming are: 1. Success following the Bottini operation depends on having perfect instruments; a good battery; the necessary skill, and the employment of a proper technique. 2. In suitable cases the Bottini is the safest and best radical operation thus far advised for the relief of prostatic hypertrophy. 3. It is often very efficacious in advanced cases of obstruction as a palliative measure, rendering catheterism easy and painless, relieving spasm; lessening the tendency to constipation, and improving the general health. 4. It is of especial service in the beginning of obstructive symptoms due to hypertrophy of the prostate gland, and may be regarded as a means of preventing catheter life. 5. It is indicated in all forms of hypertrophy except where there is a valvular formation, or where there is an enormous overgrowth of the three lobes, associated with tumor formation giving rise to a pouch, both above and below the prostate gland. 6. Where the bladder is hopelessly damaged, together with a general atheromatous condition of the blood vessels, associated with polyuria, results are negative. 7. Pyelitis is not a contraindication to a resort to the operation. 8. The character of the prostatic growth has no bearing on the results of the operation. The ligation of the internal iliac arteries for the relief of hypertrophy of the prostate gland, first recommended by Bier, has been tried by several surgeons with very unfavorable results. The benefit derived from the operation is slight, and the mortality higher than that following prostatectomy. Thus far, the results derived from angioneurectomy have been negative. I have frequently witnessed the operation of perineal prostatectomy when performed by others, and have on various occasions resorted to it, but I have found that nothing was gained beyond the temporary improvement that might naturally be expected to follow rest and drainage.

29. **Puerperal Insanity.**—Lane's article is largely an argument against the existence of puerperal insanity as a distinct disease and gives a calculation of the number of females of child-bearing age suffering from insanity and the cases of puerperal insanity reported in the Boston Insane Hospital. He finds that the number of cases among child-bearing women are rarer than among women in general at child-bearing age. It would be a good risk to insure a pregnant woman against insanity or at least against commitment for insanity. The latter part of his paper is made up of reports of cases.

30. **Home Treatment of Tuberculosis.**—The advantages of treating tuberculosis at home are that the patient avoids the risk of double radical change and makes his recovery under conditions which can be continued. The influence of familiar surroundings are also to be considered as well as the pecuniary factors. If other things were equal, which they are not, he is inclined to believe the sanatorium treatment in the Rockies or Alps, conducted on the same line as the Dettweiler at Falkenstein, and with the same stage and class of cases, would produce better results than the sanatorium in our home climates, but the majority must, if the hygienic treatment is attempted at all, undertake it near home.

37. **Ear Troubles in Children.**—Yearsley insists on the importance of early recognition of ear troubles, especially deafness, which he thinks should be suspected whenever the child is slow in learning to talk. If it passes its first two years without acquiring a few simple words, it is probably the subject of defective hearing. Pains in the ears in a child may be very variable, but it is most important to know the condition. If the general practitioner who is first to see the case, can exclude or diagnose ear disease, he will have the satisfaction of saving the patient much possible future suffering and himself much annoyance.

38. **Thermol.**—This drug, which has its chemical composition $(C_{14} H_{15} No_3)$, is recognized by Rosenthal in combination with other drugs as an antipyretic in fevers of children. He thinks we have in it a perfectly safe antipyretic of known value with also hypnotic and analgesic powers.

45. **Angiosarcoma of the Brain.**—After first considering the indefiniteness of pathologic symptoms in cases of brain tumor, Perkins reports a case in which the diagnosis of angiosarcoma could be definitely made but in which no trace of special connections with blood vessels, either endothelial or epithelial could be made out. The diagnosis of cerebral tumor was made from the usual symptoms. The autopsy revealed a growth of the right frontal lobe without metastases, which microscopically, from the character and arrangement of tumor cells, their lack of processes, the minimal amount of stroma and sharply defined limitations from the brain substance, resembled sarcoma; the abundance of vessels throughout the mass, suggesting angiosarcoma in the absence of infiltration; lack of nerve cells, apparent absence of glia fibers, were against the diagnosis of glioma. He concludes his paper with remarks on the nomenclature of brain tumors and a brief review of the opinions of others.

46. **Epilepsy.**—The morbid anatomy of epilepsy as illustrated by 130 autopsies is discussed by Ohlmacher. The findings seem to him to justify his elsewhere expressed opinion as to the close association between this nervous symptom and the peculiar condition known as the lymphatic constitution or lymphatism. He, however, says that one must not expect to find a complete picture of lymphatism, with the persistent hyperplastic thymus, general lymphadenoid hyperplasia, and arterial hyperplasia is not to be found in these conditions, as a rule, for it occurs only in children or young adults. In older persons or those dying of wasting diseases or epileptic exhaustion the evidences of lymphatism are masked and seen only in such ineradicable features as narrowed arteries or the osseous deformities of rickets. Of 71 cases classified as idiopathic and lymphatic epileptics a goodly number proved typical examples. The predominant brain change accompanying this class of cases is a gliosis of the cerebrum taking the form of diffuse superficial cerebral gliosis either hypertrophic or atrophic or a localized sclerosis affecting certain parts, particularly the horns of Ammon and the hipocampal gyri. He is inclined to the opinion that this is in some way related to intracranial pressure and it is pretty well established that lymphatism is one of the consequences of rickets and we may come to rickets as the ultimate basis of epilepsy and allied nervous disorders. If this be the case, the problem of dealing with idiopathic epilepsy resolves itself into one of the combating infantile rickets, which is probably a nutritious and infectious disorder, preventable by proper dietary and hygienic precautions in infancy. The other class were those of infantile cerebral paralysis, which amounted to 15 per cent. of the whole, the senile epilepsy, represented by 8 cases, showing brain lesions or other localized arterial gliosis from arterial sclerosis of the cerebral arteries or foci of cerebral softening. There were 6 cases of senile epilepsy, or 5 per cent., 3 of cardiac epilepsy, connected with advanced cardiac changes which are supposed to be of direct causal relation, 2 of paralytic dementia, 1 each of alcoholic and uremic epilepsy, and 1 due to cerebral tumor, a cystic glioma of cerebrum.

51. **Ideals in Appendicitis.**—The ideals in appendicitis operations are, according to Scott, a model patient, who must be of high intelligence and in good physical condition, and an appendix with a reasonably long mesentery allowing free motion; the disease should be limited to the structures beneath the peritoneum and at the stage not yet threatening rupture. The adipose tissue of the abdominal wall should be thin and the fascia well developed. The surroundings should be such as to insure aseptic operation with all that this implies. This

is best secured in well-appointed hospitals, and a nurse that understands the ideals to be attained and the methods of achievement. Lastly, the surgeon should be a keen diagnostician and careful even to the smallest details, must have not only a good surgical ability, but added to this, dexterity and experience, so that he can perform the operation through the smallest possible incision. When all these requisites have been obtained, the traumatism of the internal parts will be limited to a mere dimple upon the head of the colon; there will be no free raw surface to form adhesions, and no necessity of absolute quiet of the intestine for the purpose of repair in aseptic operations. The only active factor to be considered is traumatism of the abdominal wall. The rapidity of the convalescence is inversely proportional to the length of the incision in the fascia, which in these favorable cases will not be over three-fourths, perhaps not over one-half inch, the elasticity of the parts being such that it is possible to introduce the finger through the dilated incision. An illustration of these ideals he gives in his own case in which he was operated upon, leaving the hospital after four and one-half days; on the sixth day he made his hospital round, transacted business and called upon his physician.

59. **Occlusion of Duodenum.**—Cordes reports a case, the fifty-seventh, according to her researches in the literature, of congenital occlusion of the duodenum, and tabulates all the cases she has found. She discusses the symptoms and says that, whatever may be said in regard to stricture of the intestine in other regions, it seems clear that volvulus and fetal peritonitis can not explain the large number of cases of occlusion of the duodenum. A number of facts, such as the repeated occurrence of this occlusion near the site of the papilla, the existence in probably more than one case of anomalies of the duct system, the absence of Brunner's glands in one case and the striking absence of any sign of disease to which the condition is traceable and other malformations than that of the duodenum in a certain number of cases, lead her to think that an error of development not yet explained may underlie this condition.

60.—This article was abstracted in THE JOURNAL of March 2, p. 592.

74. **Bullet Wound of the Spine.**—The case reported by Sailer is that of a man struck four years ago by a Mauser bullet which passed through the spinal cord in the lumbar and sacral region. There was immediate paraplegia and some years later severe fulgurant pains in the limbs. To relieve the latter, laminectomy was performed and a greatly thickened dura was incised; the operation gave great relief. Subsequently some improvement occurred and finally there was only total anesthesia and paralysis of the right limb and lower portion of the right thigh, and total anesthesia of the left foot, movement at both hip joints and left knee joint and slight improvement of the left foot and toes; total anesthesia over the sacral area, and hyperthesia of the perineal region. Sexual reflexes of the patient were only partially impaired. The interesting features of the case are the localization of injury of the spinal cord, the satisfactory results of operation three years after receipt of injury, and a curious sensory phenomenon (allochiria) shortly after the operation, while improvement was in progress. The localization in the cord is discussed at length with considerations bearing on the physiologic centers. He is certain that the anterior cornu, or the anterior root proceeding from it, was intact on the right side of the level of the first lumbar segment. The bullet probably entered about the level of the lower portion of the second lumbar segment, involving the third and fourth and possibly the fifth lumbar segments, but not the first sacral, or any of the segments below it on the right side. On the left side the first, second and third lumbar segments were certainly intact, as shown by muscular innervation, the fourth lumbar segment was partially involved, and the fifth probably totally destroyed. A study of the sensory areas also bears out this diagnosis. There is probably hemorrhage in the central portion giving rise to disassociation of sensations. The allochiria mentioned was observed thirty-nine days after operation and lasted about three days.

75. **Subjective Healing.**—Baker discusses the fads of subjective healing and suggests that we should consider the human invalid not the mere victim of a special affection, but study the entire individual in the diagnosis. A consideration of these facts shows the uselessness of wearing people out with drugs and cultivating too much dependence on them. It also shows the dangers of extreme concentration of a purely subjective order and the psychical elation which has not been given solid basis to sustain it. The "healer" often seems to make a good start in the right direction with the individual, but soon fails from lack of knowledge of physiology and pathology. Unless the body has been remedied and the mind furnished and steadied, and conduct ordered in accordance with actual needs, no cure worthy of the name can be expected from either materialist or idealist. The neurologist and psychologist should determine how far results which are now secured haphazard can be obtained by proper scientific practice. People, especially when young, should be encouraged to most sedulously cultivate bodily endurance, mental growth and freedom, and spiritual self-reliance, faith in inductive science, rather than trust in dogmatic deduction, with the hope that where now there is such readiness to develop morbid introspection and flaccidity of the mind a better state can be produced.

83. **Oral Neuroses.**—The conditions described under this head by Goodale is divided by him into the following: 1, herpes zoster; 2, herpes buccalis and lingualis; herpes facialis; erythema exsudativum multiforme, or bullosum; 3, erythyema nodosum; purpura rheumatica; 4. stomatitis neurotica chronica of Jacobi; 5, dermatitis herpetiformis of Duhring (of doubtful position); 6, pemphigus. Of the above conditions the herpes forms, erythema nodosum and purpura rheumatica are all defined clearly, but with the erythema bullosum, dermatitis herpetiformis and stomatitis neurotica chronica much confusion exists. Erythema bullosum is an angioneurotic inflammation, generally afebrile, is characterized by eruptions of one or more vesicles upon a hyperemic basis, without characteristic grouping, enlarging rapidly by peripheral extension; it forms bullæ of one or two centimeters in diameter, the contents of which are at first clear, later cloudy, and evacuated by maceration and rupture of their epithelial covering, leaving a moderately sore, but not spontaneously painful base, which heals in from one to four weeks without a scar. Dermatitis herpetiformis is a chronic, probably infectious condition characterized by more or less general eruption upon the skin and mucous membrane of lesions of multiform type, with pronounced burning or itching sensations and having a protracted course with temporary exacerbations and remissions, and little existing disturbance. Stomatitis neurotica chronica is a chronic, afebrile affection, occurring generally in neurasthenics and characterized by more or less general outbreak of bullæ upon the oral and lingual mucous membrane preceded at times by local reddening, somewhat painful, not pruritic, and various symptoms of nervous disturbance. Pemphigus is a term applied to various forms, probably infectious and distinct, but differing in their etiology and having a common characteristic eruption of clear non-purulent bullæ on an unreddened or very slightly reddened skin or mucous membrane, in regular sequence, without angiogenic form, characteristic grouping, distribution or localization, with little or no local subjective symptoms and having an acute onset and tendency to recurrence and generally attended with marked disturbance of the general health. These characteristics given above may be regarded as representative type forms, but another source of confusion is the various meaning attached to the term herpes, pemphigus, etc. The rest of his paper is given up to a description of the herpes, erythema, and other disorders of the mouth.

94. **Malignant Disease of the Breast.**—Warren's article describes the condition and Halsted's operation for its relief. As regards the results he thinks that if examination shows no recurrence within three years the cure may be regarded as certain. Taking the average results of the present time, he says, we are safe in assuming that a cure can be affected in at least 30 per cent. of the cases operated upon, though this percentage depends upon the class of cases selected. There is a type of cases which almost always may be regarded as favor-

able, that is, those which have been under observation for several months and have made no progress. In nearly all cases of cure in his experience the microscopist has given a diagnosis of scirrhus cancer. The question whether we should try a post-operative treatment to prevent recurrence is mentioned and he suggests the use of mammary extract as possibly producing a soil antagonistic to the return of the disease. He has not yet, however, enough experience to express a definite opinion as to its value. He has seen improvement in reabsorption of recurrent nodules from the use of the thyroid extract and he says, however, as regards the subcutaneous use of alcohol and pyoktanin that we should bear in mind that cancer nodules may disappear spontaneously.

104.—This article has appeared elsewhere. See abstract in The Journal of April 6, No. 79, p. 995.

114. **Human Tails.**—The reported cases of caudal appendages in man comprises a most heterogeneous class. Anything appended to the sacral or coccygeal region is described as tails. There are, however, a great many cases, Harrison says, in which the anatomical relations are such as to indicate that the growth owes its existence to the persistence of at least part of the vestigial tail found in the human embryo. The case he reports appears to be such a one. The subject generally is discussed at length and the way in which the abnormality appears is theorized out. He concludes with Keibel that while as far as outward form is concerned the embryologic tail disappears, largely as a result of growth of the extremities and gluteal region, a certain amount of regressive change takes place in the caudal appendix itself. This is evident not only in the absorption of the caudal filament but also in the reduction of all the bone structures of the vertebral portion of the tail, that is, the vertebræ, muscles, segments of spinal ganglia and blood vessels. In this tendency to reduction the resemblance between human and mammalian tails also holds. The soft or boneless tails are clearly not due to multiplication of vertebræ or to the persistence of all which are developed in the vertebræ, but, as he first suggested, are to be regarded as persistent caudal filaments.

116. **Bilateral Relation of the Cerebral Cortex.**—Mellus reports experiments made by removal of portions of the cortex in the monkey, observing the functional lesions and studying the lateral degenerative processes. The most striking feature is the large number of degenerated fibers passing from the cortical lesions over the middle line in the corpus callosum and down the internal capsule of the opposite side. With the exception of those fibers going to the superior temporal convolution of the opposite side, the fibers in this experiment all pass into the thalamus. In a few animals in which practically the same area was extirpated some of the degenerated fibers found in the internal capsule of the opposite side can be followed through the pons and medulla into the cervical region of the cord, where they disappear. From this he concludes that a vast number of the projection fibers arising in the motor cortex end in the thalamus and especially those of the area in which more or less bilateral movements are represented. These movements are mostly facial, and he thinks this has some bearing on the function of the thalamus. It has been suggested that the thalamus is the center for reflex or emotional movements, and the facts here stated may explain the play of the features as the result of emotion when voluntary movement is impossible. In many extensive lesions of the internal capsule fibers passing into the thalamus, even on the side of the lesion, might easily escape injury, even if bilateral control of the thalamus were improbable. The presence of degenerate fibers in the lateral geniculate bodies in this case is suggested to be possibly due to these having the function of voluntary inhibition of certain visual reflexes.

120. **Nuclei Pontis.**—The summary of Long's article on the development of the nuclei pontis is given as follows: "The main nucleus pontis is situated on the central surface of the rhombencephalon at the level of the pontal flexure. In the specimens the nuclei pontis are first seen on the surface and in the ventral part of the mantle layer of the lateral part of the pons Varolii. In the second embryo the nucleus pontis ventralis extends across the middle line of the rhombencephalon and the nuclei pontis dorsales are separated from its lateral part by the ventral fiber bundle. The nuclei pontis dorsales next form two solid masses, reaching almost to the middle line. They are still separated by the ventral fiber bundle from the nucleus pontis ventralis, except at extreme lateral ends, where they are continuous with each other. Next the nucleus pontis becomes a solid shell on the ventral surface cut by a small branch from the ventral fiber bundle. After the sixth month the pons consists mainly of fibers and scattered groups of cells, which increase at the expense of the dorsal part of the nuclei while a narrow ventral nucleus or cell-mass is left on the surface.

121. **The Gall-Bladder.**—Sudler's article is chiefly devoted to a description of the lymphatic and finer blood-supply of the gall-bladder, described in detail.

123. **Liver Lymphatics.**—From the observations here reported, Mall concludes that: 1. The lymphatics of the liver arise from the perilobular lymph spaces and that these communicate directly with the perivascular lymph spaces. 2. That the lymph reaches these spaces by a process of filtration through openings which are normally present in the capillary walls of the liver. Furthermore, the fluid injected into the lymphatics from the bile duct leaves the duct as it enters the lobule and is at once taken up by the lymph radicals and perilobular lymph spaces, and from them extends, as a secondary injection, to the perivascular lymph spaces, and often into the blood capillaries of the lobule. The larger lymphatics accompanying the portal vein arise between the lobules near their bases, while those accompanying the hepatic vein do not arise within the lobule but around the larger sublobular veins.

139. **Spectacles.**—This article is of interest as giving the views of an optician in regard to the fitting of spectacles. Meyer mentions the harm coming from patients trying to fit themselves, and thinks that even few physicians and oculists realize the importance of the careful filling of their prescriptions, not only as regards perfect lenses ordered, but also the making of the frames and adjusting them to the correct position before the eye. The distress produced by inaccurately adjusted lenses, he says, is unappreciated by those who have not felt it. He gives an instance of a lady who traveled 100 miles to her oculist, suffering with headache and gastric disturbance, and was completely relieved by the prescription: "Reduce the angle of the glasses 5 degrees." The fact that the glasses tilted a few degrees more than they should gave the effect probably of a cylinder in the longitudinal meridian, producing an astigmatic effect, which she did not naturally have. He says that opticians usually do not charge for adjusting glasses when they get out of shape, as it takes only a few seconds of their time, but are amply repaid in the expression of satisfaction of those that have received the benefit. He also discusses the peculiarities of the optician's patient and believes that the average tradesman in dealing with them would consider them all cranks. The skill of the optician in meeting the demands of these is the secret of his success.

141. **Asthma.**—Jack considers asthma not a disease by itself, only a symptom of an abnormal biochemical and complex pathologic process originating usually in the intestinal canal, with long-standing indigestion, toxemia, faulty absorption, metabolism producing toxemia of lymphagenous chyle that generates an unstable blood, characterized by extremely numerous and alarming paroxysmal morphologic changes, often alternating between lymphocytosis and intestinal toxemia leucocytosis, or marked anemia; the affection is accompanied anatomically by hyperplasia of the lymphatic and glandular structures and clinically by a most wretched and agonizing dyspnea. The characteristic pathologic feature of asthma is the unstableness of its blood. The main part of his article is given to describing the different forms of asthmatic conditions, such as asthmatic lymphocytosis, intestinal toxemic leucocytosis and anemia.

154. **Rectal Prolapse.**—This article describes the method of treatment of complete rectal prolapse of the first and second degrees, when the prolapse is due to alteration in the passive supports of the lower portion of the rectum. After preparing

the patient by cleaning out the bowels, syringing the parts, and asepsis, the prolapse is drawn down and measured. While it is down the semicircular incision is made midway between the anus and coccyx and carried between the muscles of the levator ani until the retrorectal space is reached. With the finger or a pair of blunt scissors the rectum is then separated from the sacrum as high up as the distance which it protrudes from the anus. With the dull curette the fatty or cellular tissues are scraped off the anterior surface of the sacrum and the prolapse then reduced. The assistant's finger carried through the anus inverts the gut, bringing it out between the incision made between the anus and sacrum to the same extent as the prolapse. While held in this position and flattened out long silkworm gut sutures are passed from its muscular walls from one side to the other, one above the other, and transversely. The only precaution necessary is to not carry them deep enough to involve the mucous membrane while introducing them. However, the external cellular tissue should be removed. The sutures are placed about one-half an inch apart until the whole protrusion is covered, the ends being left loose. After all the sutures necessary have been introduced, each end of the higher suture is threaded with a long curved needle, which is carried upward through the division between the sacrum and rectum and brought out at the highest point of this cavity through the ligaments and fascia upon one side of the sacrum. The other is dealt with in like manner, and the lower sutures in succeeding order are also carried up through the wound and brought out at lower levels until they all have been so treated. When these sutures are made taut they will carry the rectum upward and holding it in apposition with the fresh surface edges in normal position. If it can be held here until the normal tone of the muscular supports below has been restored the cure will be permanent. The sutures are brought across the sacrum over a strip of iodoform gauze laid upon the skin in order to prevent the threads cutting into it, and left for ten days or longer. After these have been thus tied, the sphincter muscle is much relaxed; it is well to pass a kangaroo tendon around the rectum just above the margin of the external sphincter, entering it in the original wound and sutured in the same wound. After this is done the wound is closed with a chromicized catgut suture for the muscles and plain catgut or silkworm for the skin. Cases operated upon in this way have been observed for three years. Five out of the nine were old and very chronic cases, one having existed for eighteen years, and with one exception there have been no symptoms of recurrence. When prolapse occurs high up in the peritoneal portions of the rectum an abdominal sigmoidopexy is advisable and he describes the operation.

155. **Resection of Vena Dorsalis Penis.**—Lydston criticises those who have claimed to have cured patients of impotence from ligation of this vessel, and thinks we would have probably better results from its resection and that this ligation as a rule has nothing to do with the brilliant results thus reported.

Skiagraphy and Fractures: Especially in Their Medicolegal Relation. C. H. Golding-Bird.—After first mentioning the dangers of the popular misuse of the X-ray, Golding-Bird discusses the subject from the surgeon's point of view. While no one will question the value of the method in the diagnosis, its use is unnecessary in the larger proportion of cases one is called upon to treat, yet there is a certain class of doubtful cases where it is most desirable. These are of two kinds, one in which though certain of fracture, there is a doubt as to the exact locality, its direction, or perhaps its involvement of a joint. The other, where the existence of fracture is doubtful, and while this doubt may not necessarily modify the line of treatment, yet should the patient get skiagraphed on his own account, and be able to demonstrate a fracture, a suit for malpractice might arise or other embarrassment to the surgeon. Of this second class, fractures of the fibula and vertical or transverse fractures anywhere and certain forms of fractures around the hip are examples. Thus, he mentions Pott's fracture, which may occur without characteristic deformity and be diagnosed as severe sprain. A vertical fracture involving the knee-joint, a purely transverse fracture without displacement, notably in the lower end of the tibia in which the patient is still able to stand and impacted fractures of the hip are hard to be certain of. Patients, moreover, especially private ones, insist on positive knowledge of the state of their bones after injury. People have a morbid dread of bone injuries and great comfort may be given by the mere assurance that the bone is not injured. Therefore, the skiagraph may be very useful as a diagnostic evidence to the surgeon to satisfy his patient. It would be a bad thing if the diagnosis were relegated entirely to this method, and over-reliance upon it is also to be deprecated. It is only as a subsidiary generally that the skiagraph should be employed, and even then its evidence should be received with caution, and only after due interpretation by someone whose experience warrants his speaking with authority. Another use of the X-ray is to judge the results of one's handiwork and Golding-Bird thinks this is rather unreliable. The laity, and often some physicians, have a very poor idea of the actual conditions even of successful cases of simple fracture. Functional performance may be perfect and yet the X-ray show a decided deformity. The skiagraphs show that in order to satisfy esthetic requirements almost every case should be operated upon and the bones adapted by screws, wires or by some other means. If the final appeal is not to utility, but to the beauty of the bone scar, then every case must be thus treated. Before deciding upon the value of the skiagraph, we must inquire whether it really represents things as they really are, and this is a further argument against employing it as a critic of a surgeon's work. He asks, can skiagraphs show fracture where none exists, and answers, that it can. Epiphyseal lines on the long bones, the end of the ulner for example, have been mistaken for fractures. Impacted fracture of the neck of the thigh can be imitated by taking a foreshortened view. Fracture through the base of the olecranon is simulated always where the light is directly over the bend of the elbow, the plate being posterior. The band of light is due to the rays penetrating the joint; a lateral skiagraph destroys the illusion. The acromio-clavicular joint resembles a fracture and has been mistaken for such. The appearance of gradual thickening of the bone can be produced at will. He is indebted for these and other references to the report of the American Surgical Association on the medicolegal relations of the X-ray, in the *American Journal of Medical Sciences*, for July, 1900. The second question: Is it possible to miss seeing a fracture? Yes; though rarely. Usually it is recognized by irregularity of the bone outline, but where this is not easily seen, attention to the outline of the medullary cavity generally shows it. In the ribs, especially the lower ones, because of the shadow of viscera, in the spine between the fourth and twelfth vertebræ, because of mediastinal structures, fractures may be overlooked. In the ends of very young bones centers of ossification may be mistaken for detached bone or vice versa. Anatomical depth, as in the hip, has caused trouble in recognizing fractures. The base of the skull is hardly likely to receive aid from the skiagraph. Is it possible to show fracture as still existing, though long united? He states that it is. Early callus will not show, and for the first three months the unpracticed observer might not see it distinctly. Similarly the line of union will seem to be one of separation. Can distortion be produced? Yes; by foreshortening. The appearance of gradual expansion of the bone can easily be produced by want of parallelism between the plate and limb and may be read as indicating injury. Looking at the subject from the patient's point of view the question of X-ray and fracture becomes a very serious one. It is not possible to prevent the use of the X-ray by a patient; therefore, instead of awaiting the attack, the surgeon should disarm suspicion first. He should be told, moreover, that the new photography is no measure of the cure, that the setting of fractures is not a piece of accurate cabinet-work; the people should be instructed in the uncertain indications that skiagraphy gives. The lawyer should learn that it is not a reliable witness. It can not stand alone even for everyday practice or diagnosis, still less can its testimony be invoked for the defense or attack in a court of law.

British Medical Journal, June 15.

Hepatic Inadequacy and Its Relation to Irregular Gout. I. Burney Yeo.—The subject of irregular gout is treated by Yeo, putting the common forms under the general head of hepatic inadequacy. The author begins by defining hepatic inadequacy, by which he means special disturbance of the function of the liver, which while stopping short of giving rise to what are generally known and accepted as diseases of the liver, lead yet to impairment of general health. In this way, he thinks, arise almost all those cases which are known as irregular gout. The uric acid theory he finds inadequate and he calls attention to the fact, as he says, that physiologic and chemical research is not always as helpful to clinical medicine as it might be, unless it is carried out in what may be called a clinical spirit without dogmatically imposing its conclusions on physiology. As instance of the failure of such research to aid the physician he calls attention to the condemnation of calomel as a cholagogue by the Edinburgh committee some years ago and shows that the practice of medicine has rejected that conclusion. Another point is the condemnation of the use of sodium salts and alkalines in the treatment of gout and the gouty state which has led to another series of practical mistakes. He quotes especially H. M. Lyman as supporting this view, that the alkalies and sodium salts are of value in the gouty states. In answer to the question what symptoms are referable to hepatic inadequacy presented by patients with irregular gout he mentions the following: In the first place the feces are often pale, from the absence of bile-coloring matter, and often very offensive. There is frequently constipation, but there may be diarrhea, and some liver enlargement, with tenderness, muddy complexion, yellowish conjunctiva and a sweet-bitter taste in the mouth with loss of appetite. The urine is highly colored and often of high specific gravity, and usually extremely acid. On boiling and adding nitric acid, various shades of mahogany color are developed and in some cases the urine looks almost as black as ink. This is very common in the gouty state. It is also commonly found in functional and malignant hepatic disease. There is another type of hepatic inadequacy, which he calls the liver of the seaside, which is hard to explain, but is observed in seaside resorts, and is relieved by change of residence. He believes that some subtle influence exists, checking the activity of the bile cells, and thus develops hepatic inadequacy. He mentions other facts which bear out this idea. There are physiologic reasons as well as clinical for incriminating the liver in the production of the gouty state. The liver is specially concerned in the metabolism of carbohydrates—its glycogenic function,—and also in the metabolism of nitrogenous material and in the formation of urea and uric acid. In the gouty the glycogenic function is often disturbed and restored by alkaline medication, and he asks, is it not reasonable to believe that another function of the liver carried on side by side with this one is also prone to be disturbed? He also finds the production of the bile disturbed in the gouty. As regards the diet of these cases he does not find a vegetable diet specially applicable, but he has seen great improvement with the exclusive or nearly exclusive diet of pounded meat and full draughts of hot water. It is the simplest diet that can be made and this is the principle which he thinks should be followed. The extremely simple food, limited in amount, causing digestive ease, means also freedom from goutiness. Nature finds some mischief still for idle food to do, paraphrasing Dr. Watts. There is much also in the quality and cooking of the food; often more than in the kind. There is a general impression that gouty people do not take enough exercise. That is not his experience. Excessive muscular activity leads to excess in food and then trouble comes. The advice to shake up the liver is bad.

On the Protection from Water-borne Disease Afforded by the Pasteur Chamberland and Berkefeld Filters. W. H. Horrocks.—Experiments with the Berkefeld and Chamberland filters are detailed by Horrocks, who sums up his conclusions as follows: "1. Typhoid bacilli are not able to grow through the walls of a Pasteur-Chamberland candle, and if proper care be taken to prevent the direct passage of the bacilli, through flaws in the material or imperfections in the fittings, the Pasteur-Chamberland filter ought to give complete protection from water-borne enteric fever 2. Typhoid bacilli can grow through the walls of Berkefeld candles, probably owing to the larger size of the lacunar spaces and the consequently diminished immobilizing and devitalizing influences. The time required for the typhoid bacilli to traverse a candle varies between four and eleven days, and appears to be largely dependent on the nutriment supplied to the organisms by the medium in which they exist. In order to obtain complete protection from water-borne enteric fever, when employing Berkefeld filters, it is necessary to sterilize the candles in boiling water every third day."

The Lancet, June 8.

An Explanation of the Vulnerability of the Apices in Tuberculosis of the Lungs. E. H. Colbeck and Eric Pritchard.—The vulnerability of the apices to tuberculosis is discussed at length by the authors, who find that according to their deductions, it is largely determined by alteration in the shape of the chest in conjunction with deformity or thinning of the musculature of the shoulder girdle. Woods-Hutchinson, who has worked at the subject from the side of comparative morphology and pathology,, expresses similar views. The importance of alterations in the shape of the chest and the abnormal condition of the shoulder girdle lies in the modification which these changes induce in the dynamic relations of the superior aperture of the thorax, whereby the movements of the apices become inverted in their relations to normal respiratory rhythm. It is this altered dynamic relation that furnishes the conditions which favors the lodgment of extraneous matter in the upper lobes of the lungs. The exact position of the site of the deposit is determined largely by the distance the apex rises above the border of the first rib, inasmuch as it is this extra-thoracic portion of lung which is acted upon by the forces that give rise to inverted movement. Since the apex rises from one inch to one and one-half inches above the border at the first rib, they conclude that the site of the deposit will be situated from one inch to one and one-half inches above the summit of the lung. This same method of reasoning probably explains proclivity to tuberculous disease of the basal lobe of the lung in cattle, which is also likely due to mechanical causes. The practical bearing of the theory is the enormous importance of developing the muscles of the shoulder girdle with the object of pulling the chest into shape, as Woods-Hutchinson puts it. To this end tree-climbing, ball-throwing, horizontal ladder and bar exercise and any muscular exercise should be sedulously and systematically carried out. The authors suggest that the subject is pertinent also to explain other abnormal conditions in the apex and call attention to development of emphysema in this situation.

Annales de Dermatologie (Paris), May.

Disseminated Gangrene of the Skin in Children. A. Veillon.—A case is described and illustrated which proves that disseminated gangrene of the skin in children is not an isolated affection. From a clinical as well as a pathogenic point of view, the disease should be classed with true gangrene, and bacteriology reveals that it is due to the proliferation in the tissues of strictly anaerobic microbes, and is hence, a mortification in the tissues with a special fermentation, besides the necrobiosis. The writer has found the bacillus ramosus in all the cases of gangrene he has examined; in the present case it was associated with the staphylococcus.

Persisting Syphilitic Lesions Despite Intense Mercurialization. H. Hallopeau.—Syphilitic lesions on the soles of the feet or the palms of the hands are peculiarly rebellious to specific treatment, both general and local. Hallopeau describes a case and points out that the differences in structure of the skin in various parts of the body should be borne in mind in attempting to explain the pathogenesis of its alterations. In these cases the outer layer of the skin is so dense that the mercury and iodin applied locally or brought in the circulation, are unable to penetrate the multiple rows of cells, and thus fail to reach the infectious elements in the epidermis.

Archives Gen. de Medecine (Paris), May.

Grippal Cerebrospinal Meningitis. E. Sacquépée.—The analogy is so close between the clinical picture of epidemic and grippal cerebrospinal meningitis that they can be differentiated only by bacteriologic examination. The lesions seem to be identical in nature and degree, but the grippal affection is apparently a milder infection. Six out of nine patients observed by Sacquépée recovered. Lumbar puncture had an unmistakably favorable effect on the course of the disease, and sodium salicylate and quinin also proved useful.

Bulletin Medical (Paris), May 25.

Pathogenesis of Floating Kidney. M. T. Rosenthal.—The displacement of the organ is not the essential cause of the disturbances in case of floating kidney, but rather a primary congestion of the organ. The digestive troubles are due to the congested and hence enlarged organ. This congestion is especially liable to occur in arthritic subjects, even in the absence of enteroptosis. The oppression and pains always appear in the two or three days preceding menstruation. In patients with insufficient menstruation the pains persist during the entire period and may outlast it. Another cause of floating kidney is an accidental displacement or luxation caused by some unusual exertion, such as lifting a heavy weight, an effort to stand on the tips of the toes or a fall on the feet. Nephropexy fails to relieve many of these cases as the recurring congestion is the real cause of the trouble. Massage is the only rational and successful method of treating it, commencing at the lower pole of the kidney and working upward. A cold compress is kept on all night, with an abdominal band during the day. Twenty to forty-five séances are usually required. The first few are liable to be painful, and should last only five or six minutes. By the twelfth séance all pain and the dragging sensation are entirely banished.

Journal de Physiologie (Paris), March.

Technique of Thyroid Grafts. H. Cristiani.—The secret of success in transplanting the thyroid gland is to graft it in a number of long, flat pieces, not entire. These grafts heal in place and continue to develop normally, whether implanted in the peritoneum, abdominal wall, skin of back or front of thorax. Cristiani states that his attempts have been invariably successful and in a large variety of mammals.

Serum Treatment of Glanders in Man. A. Dupuy.—A single case is reported. The patient left the hospital cured in six months, after thirteen subcutaneous injections of 20 c.c. of normal beef serum in the first three weeks of the disease.

Revue Hebd. de Laryngologie (Bordeaux), May 25.

Pathogenesis and Treatment of Nasal Hydrorrhea. Brindel.—Microscopic examination of the nasal mucosa in cases of spasmodic coryza with nasal hydrorrhea, shows an accumulation of round cells, epithelial desquamation, multiplication of the blood vessels and great dilatation of the veins. These changes are accompanied by extravasation of the blood in the mucosa and transudation of the serum through the meshes of the connective tissue. The hydrorrhea is therefore a kind of edema with immediate excretion of the extravasated fluid. The mucosa becomes more or less degenerated and the most favorable treatment is by single or double turbinotomy. No glands are visible in the tissues removed, in four-fifths of the cases. Brindel has recently treated a case in which the tissues removed by the turbinotomy were tubercular, showing that a primary, non-ulcerative tuberculosis of the nasal fossa may deceptively simulate spasmodic coryza with hydrorrhea and may be cured with the same treatment, that is, partial turbinotomy.

Revue de Gynecologie (Paris), March-April.

Surgical Perforation of the Uterus. P. Rebreyend.—The progress of modern surgery enables us to view instrumental perforations with considerable equanimity now-a-days. Simple puncture does not require operative treatment, but an actual wound demands immediate repair. This should always be done through the abdomen. The uterus should not be sacrificed except in case of irreparable lesions, or for some cause foreign to the perforation. Fourteen instances of perforation of the uterus are tabulated, with three deaths. In Stickney's case, a supposed tumor was punctured twice but proved to be merely the gravid uterus, with delivery imminent and normal. Pinard has published a case in which he punctured for a supposed tumor, finding later that it was a case of twin pregnancy with dropsy of one fetus, born later macerated. Twenty liters of fluid were removed by Tillaux from the uterus at the sixth month of pregnancy in another twin pregnancy. Mackenrodt produced a perforation by traction, Zinke with the curette. The latter healed after tamponing.

Primary Malignant Disease of Fallopian Tube. A. Boursier.—In the 38 cases collected a malignant deciduoma was found in one case, sarcoma in 5 cases and primary epithelioma in 32. The majority of the patients were between 45 and 50, none over 60 or under 40. There is no connection evident between the menopause or menstrual disturbances and the development of the tumor. Sterility was frequently noted; 7 patients had borne one child twenty to twenty-three years previously; 3 were III-parae and the others had had one or two abortions. Evidences of preceding inflammation were noted in some cases. There is no pathognomonic sign, but the tube is usually more or less round; the size depends on the amount of fluid accumulated in it. In the personal case described the tumor had been noticed for three years. It caused at first merely hypogastric pains and a watery, blood-stained discharge from the uterus, not interfering with active occupation until late in the disease. The tumor was noticed for one to three or four years in most cases, but Tuffier's patient required operation in two months after the first symptoms, Cullingworth's within four months, and Watkins' in fourteen days. The latter patient had a fibromatous uterus and each tube contained a malignant papilloma. The sero-sanguinolent vaginal discharge is continuous if the uterine ostium is permeable, and intermittent if only permeable when the fluid attains a certain pressure. If the pains subside and the tumor diminishes in size as the discharge continues, it is evident that a pocket in the tube is being emptied. But if these signs occur in a woman between 45 and 50, whose strength has been failing, they suggest the possibility of a malignant neoplasm. There is nothing characteristic about the ascites, but in case the abdominal ostium is permeable, the fluid may escape directly into the peritoneal cavity unless it is walled off around the tube. In this case a pocket will form, and in this the "salpingian vomica" will accumulate. None of the cases on record were correctly diagnosed. Veit's patient is in good health seven years, Tuffier's and the writer's, one year, and Fearne's nineteen months after operation. In all the other cases the disease recurred, and the patients succumbed. The tumor remains inclosed in the tube for a long time and hence extirpation is comparatively easy.

Congenital Polycystic Kidney. Brouha.—There is evidently some primary malformation as the basis of these cases, the non-coalition of the two halves, supplemented by retention of fluid secreted or transuded into the cavity of the secretory portion of the kidney. Study of a number of cases of congenital polycystic kidney has demonstrated that the secretion of urine in the fetus is by no means as insignificant as generally assumed, and that it is an important factor in the genesis of this condition.

Revue de Medecine (Paris), May.

Epidemic Character of Essential Zona. C. Dopter.—Three cases of zona occurring in the inmates of a certain room, confirm Dopter's theory that a primary infection alone is epidemic, but the infection may attain, naturally or by acquisition, an elective affinity for a certain segment of the spinal cord, with whose nutrition it interferes in the various organisms infected simultaneously or in turn.

Malarial Polyneuritis. Boinet.—Paraplegia and atrophy followed a stage of dull and later, acute pain in the legs in the case described. The atrophy was more marked on the left

The anesthetic zones corresponded to the segmental distribution of nerves; the plantar reflex was exaggerated, other reflexes diminished. No vasomotor disturbances were noticed. Electrotherapy is useful in these cases, with hydrotherapy, iron and iron cacodylate. Quinin is useless except in acute malaria.

Semaine Medicale (Paris), June 5.

Early Signs of Puerperal Phlebitis. A. Boissard.—The variability in the appearance, course and termination of these venous affections has convinced Boissard that they are due to different or associated infectious agents and not to the streptococcus alone. Puerperal phlebitis is increasing, and it is more frequent in private than in hospital practice. It has occurred in 16 cases in the writer's experience of 4000 accouchements at the Tenon hospital. One leg was affected in 12 cases and both legs were involved in 4. In 6 instances the phlebitis appeared between the third and the eighth day, and in 10 between the twelfth and the twenty-first. The patients were febrile at the moment of delivery in the 6 cases in which the phlebitis appeared during the first week. In 5 cases the phlebitis developed after a physiologic puerperium with no elevation of temperature at any time nor during the course of the venous affection, but commencing with the phlebitis in 3. In the course of an apparently physiologic childbed, a blood-clot forms with a slow and insidious phlebitic process in some uterine sinus or periuterine venule. From this point the embolism spreads and the lesions extend to the small pelvis and the legs. This primary focus is manifested by a pain in the uterine cornu or broad ligaments, not very severe—it must be sought for. The patient notices it on movement or on digital pressure toward the hilus of the uterus. It is constant and is always accompanied by indications of pulmonary embolism; dyspnea for twenty-four to forty-eight hours, followed by a pain in the side suggesting the onset of pleurisy, the pains radiating to the shoulder, and aggravated by compression of the phrenic nerve or anterior attachment of the diaphragm. Percussion and auscultation are negative until twenty-four hours later, when a focus of sub-crepitant, moist râles is noticed from behind, in the lower third of the thorax. An apoplectic infarct has been formed and this determines a slight effusion. This pulmonary infarction is the result of the arrival of minute emboli composed of colonies of the infectious agents, rather than of blood clots. These emboli are harmless in comparison with the emboli that develop in the course of an established phlegmasia, which kill by their size or by their suppurative nature. The harmlessness of these primary emboli is shown by the fact that the temperature does not rise. Boissard has observed that all his patients recovered whose temperature remained below 38 C. This benign embolism of the lungs is followed generally in twenty-four hours by the appearance of a phlegmasia alba dolens on the same side as the pain in the thorax. Its extent and duration are by no means proportional to the intensity of the pleuro-pulmonary manifestations. Certain families seem to display a tendency to puerperal phlebitis, usually fat women of the neuro-arthritic type, although the childbed may be apparently normal and physiologic for the first two weeks.

Beitraege z. Allgemeine Pathologie (Jena), xxix, 2.

Artificially Induced Calcareous Deposits in Organs. J. V. Kossa.—Calcareous deposits are observed in the kidney after ligature of the hilum. The calcium is evidently derived from the surrounding tissues and penetrates into the cortex through the capsule. Kossa reports experimental researches which demonstrate that this same result can be attained by chemical means. Aloin, copper sulphate, iodin and iodoform all possess this property more or less. The normal kidney can eliminate large amounts of calcium without the formation of deposits, and consequently a functional disturbance always precedes their formation. The kidney suffering from the chemical action of the poison is no longer able to excrete the total amount of the calcium brought to it in the blood, and the amount thus retained is the source of the calcium crystals visible to the naked eye in the convoluted tubules. The crystals stain yellow in a 1 to 5 per cent. solution of silver nitrate, probably from the albuminate or other organic constituents. Smaller deposits are found also in other organs.

Berliner Klinische Wochenschrift, June 3.

Segments of the Spinal Cord in the Diagnosis of Tumors. F. Krause.—Three cases are described in detail—one cured by the removal of the tumor—demonstrating the valuable information derived from the study of the symptoms in reference to the segments of the spinal cord, to determine the exact site of the tumor. Of the 32 cases of spinal tumors which have been published as operated on, 14 patients died in consequence of the operation and 18 were improved or cured. In the first 20 cases there was a mortality of 10, but there have been only 4 deaths in the last 12. In the personal case described resulting in the cure of the patient, the symptoms indicated severe compression of the cord by a slowly developing tumor inside the dura, to the rear, on the right side. The presence of the knee-jerk showed retention of normal reflex function in the second, third and fourth lumbar segments, and that the lower limit of the tumor's action could not extend below the first lumbar segment. The increased tendon reflexes on the completely paralyzed right side showed that the tumor—above the second lumbar segment—had interrupted the reflex-inhibiting influence from above. This was the only information to be derived in regard to the lower limit of the tumor. It indicated that the compression could not extend below this point. The complete paralysis of the psoas and iliacus muscles indicated that the twelfth dorsal segment must suffer also from the compression. The paralysis was of the kind due to interruption of central conductibility. The injury to the pyramidal tract from the compression of the tumor was necessarily above the first lumbar segment of the spinal cord from which the psoas and iliacus derive their innervation. There was also a distinct girdle of pains, commencing in the sacrum and passing along the upper margin of the pelvis. This region derives its innervation from the twelfth and eleventh dorsal segments. The patient complained of pains in the left leg and right thigh, suggesting irritation in twelfth dorsal and first lumbar segments. The nerve roots are intimately connected with the neighboring roots and irritation of one may entail sympathetic irritation in its neighbors. In this case the symptoms of irritation might appear two roots higher than the actual location of the tumor, but this usually occurs only in case of severe pains. The evidences of interruption in the sensory tracts were diminished sensibility and pain in the region on the left innervated by the first lumbar segment, extending nearly to the iliac crest, with modified thermic sense. Still more suggestive was an oval zone of complete anesthesia on the right side at the back, between the sacrum and the trochanter major, commencing below the iliac crest and extending to a hand's breadth above it. The absolute anesthesia at this spot indicated that three neighboring root regions were paralyzed, the twelfth dorsal segment, from which its innervation was directly derived, and also the segments immediately above and below this. While the motor paralysis extended only to the first lumbar segment, the anesthetic zone included the twelfth dorsal region, and—if we agree with Bruns—the eleventh and even the tenth segments were also involved. The upper limit of the tumor was therefore diagnosed in the tenth dorsal segment, that is, at the seventh spinous process. Its lower limit could not extend below the first lumbar segment, that is, the ninth or tenth dorsal vertebra. The soft parts were incised from the sixth to the tenth dorsal vertebra and tamponed. No ligatures were required. A space from the sixth to the ninth vertebra was opened, exposing the spinal canal for 7.5 cm. The center of the tumor was at the seventh vertebral arch corresponding to the ninth dorsal segment according to Henle; to the upper edge of the tenth according to Reid and to the eighth according to Gowers. The dura above pulsated with the respiration, the spinal cord below with the heart beat. The tumor was 17 by 15 by 11.5 mm. It was easily detached from the pia but was adherent to the dura, requiring the resection of the adherent portion 40 by 17.5 mm. in size. A depression was left in the spinal cord. The tumor did not extend far enough to compress the nerve roots. The edges of the wound in the dura were coapted above and below the site of the tumor without suturing. A drain was inserted at each end of the wound. The operation was completed in forty-five minutes. The tumor was hard as a stone, cellular, studded with numerous round calcareous deposits and round, concentrically arranged balls of cellular tissue and numerous transitional forms between these two. Considerable cerebrospinal fluid was lost, and it continued to ooze from the wound for five days, but the temperature remained normal and the patient was discharged in a month. The paralyzed limb has gradually regained its function but is still weak. There is now—a year later—no muscular paralysis, no vasomotor disturbances; the knee-jerk is normal but the plantar reflex and the abdominal wall reflex can not be induced. In the second case, the patch of absolute anesthesia was in front on the left side, at the eleventh rib, corresponding to the seventh and eighth dorsal segments. This indicated paralysis of the sixth dorsal and—according to Bruns—of the fifth dorsal segment likewise. Consequently the upper limit of the tumor must be at this point, which is opposite the fourth dorsal vertebra. The autopsy in this case confirmed the diagnosis. A carcinomatous growth was found at this point. The anesthesia was due to compression of the cord and not of the roots, in both these cases. The girdle pains in the second were at the level of the ensiform process which also harmonized with this location of the tumor. In the third case, the zone of absolute anesthesia extended in front on the left side to the sixth intercostal space; at the back, to the seventh dorsal vertebra, both pointing to the sixth dorsal segment as the portion of the spinal cord affected. On the right side, it extended in front to the eighth rib and at the back, to the tenth dorsal vertebra, pointing to the eighth dorsal segment. The autopsy disclosed that on the right side the tumor had encroached on the ligamentum denticulatum and had thus exerted direct pressure on the nerve roots in the region, especially on the sixth dorsal nerve at its root. Compression of this region produces the same phenomena of anesthesia as if the sixth dorsal segment, in which it originates, were sympathetically affected. The difficulty in the diagnosis in this case was due to the girdle pains, which corresponded to the sixth and seventh dorsal segments and extended along the costal arch to the stomach. Like the zone of hyperesthesia, the girdle pains indicate irritation of the posterior roots. The compression of the roots or of the segment is sufficient to induce irritation but not to cause suspension of conductibility. A sponge dipped in hot water and applied to the spine was felt as pain between the fifth and the ninth dorsal vertebræ on the left. The tumor was diagnosed in this region and it was found at the sixth dorsal vertebra. In the three cases the lack of correspondence between the upper boundaries of the nervous disturbances and the seat of the tumor was remarkable. In the first case the upper limit of the anesthetic zone was a hand's breadth above the iliac crest while the tumor was at the seventh vertebral arch, that is, 17 to 18 cm. higher. In the second case the carcinoma was at the level of the fourth dorsal vertebra. The girdle pains were on a level with the ensiform process, 17 cm. lower. The anesthetic zone commenced nearly 20 cm. farther down, at the eleventh rib. In the third case, the girdle pains were 12 cm. below the tumor at the sixth dorsal vertebra. The zone of anesthesia commenced at the tenth dorsal vertebra on the right side, and thus 13 cm. below the tumor, but on the left side, where the tumor—a sarcoma—had developed into the ligamentum denticulatum, and exerted direct pressure on the nerve roots, the location of the tumor was not much higher than the upper limits of the anesthetic zone, the distance from the sixth to the seventh dorsal vertebra being only 2.5 cm.

Centralblatt f. Gynecologie (Leipsic), April 27.

Yeast in the Treatment of Leucorrhea. W. Albert.—The disadvantages of the yeast treatment advocated recently by Landau, are all obviated by using killed cultures of yeast cells. The substance thus formed is called sterile "Dauerhefe" by the writer, which might be translated "everlasting yeast." Vaginal secretions rapidly diminish and dry up, even large erosions heal fast, and when it is injected the night before an operation, the vagina is disinfected and sterilized better than with any other preparation known to date. The yeast displays its strongest fermenting power at 35 to 40 C.—the temperature it finds in the vagina. Kossmann in a later number quotes Hippocrates to the effect that yeast was recommended in his day in gynecology. He used it cooked but Dioscorides later, preferred it uncooked. He adds "there is little new to be discovered in medicine, but as a knowledge of Greek is no longer necessary for the medical course in Germany, many wonderful new discoveries may be anticipated in the future."

May 25.

Fate of Prematurely Born, Artificially Delivered Children. F. Ahlfeld.—Tracing the history of 54 children born to 56 women with deformed pelves, Ahlfeld finds that all but five survived the first year. The parents were all of the wage-earning class. This record is much above the average.

June 1.

Ultimate Fate of a Malignant Syncytioma of the Vagina. A. O. Lindfors.—This case has been mentioned already in The Journal. One month after childbirth a malignant syncytioma was removed from the vaginal wall. There were no uterine symptoms. Lindfors reports now that the patient returned a year later with symptoms of a left pleurisy with effusion. The autopsy disclosed a large syncytioma—a malignant deciduoma—in the left lung with numerous metastases in other organs, but the genital organs were entirely free. The embolus of the placental tissue in the left lung probably arrived at the time of the vaginal lesion, but did not commence to develop until favored by a grippal catarrh a year later.

Deutsche Med. Wochenschrift (Berlin and Leipsic), June 13.

Inexplicable Intestinal Necrosis. L. Bornhaupt.—A robust young man died after two days of severe symptoms indicating intestinal obstruction and asphyxia, although there was no tenderness nor meteorism. The autopsy showed the body normal except for a patch of necrosis without demarcation, on the ileum, 50 cm. above the cecum, with a corresponding necrotic patch on the mesentery. The right pleural cavity contained a coagulum the size of two fists. As the respiratory organs were sound in every respect the cause of this hemorrhage is a mystery. It is not impossible, however, that in consequence of this hemorrhage, some mesenteric vessel became occluded by an embolus, with consecutive necrosis. A few cases are on record in which thrombosis of the mesenteric arteries produced symptoms of intestinal occlusion and hemorrhage. The contents of the central portion of the intestines in the case described were blood-stained.

Deutsche Zeitschrift f. Chirurgie (Leipsic), March.

Intracranial Complication of Middle-Ear Disease. E. Merken.—High fever and rapid pulse suggest meningitis, when they accompany symptoms of irritation, and a tempestuous course, with rapid changes in the clinical picture. In the case of an abscess the temperature is nearly normal, the pulse slow, with symptoms of paralysis, and a more insidious course may be anticipated. If the abscess is on the left side, typical disturbances in the speech follow. Encephalitis is much less frequent than abscess, and puncture or incision of an encephalitic focus apparently does little harm. With meningitic symptoms great benefit or great harm may result from an operation, and hence, the surgeon should proceed step by step. Paracentesis alone may rapidly relieve the most threatening symptoms. If no signs of suppuration can be found in the mastoid process and the symptoms grow worse, the dura or sinus can be exposed. If still no pus is found, and nothing to explain the symptoms, the brain may be punctured or even incised, proceeding even to puncture of the lateral ventricle. Meningitic symptoms in children may be caused exclusively by the ear affection.

Cysts in the Pancreas. G. Seefisch.—The clinical symptoms in four cases were violent subjective disturbances at first, mostly gastric, ranging from a mere sensation of oppression to intense pains, vomiting and signs of retention; emaciation; development of a tumor in the epigastric region, usually towards the left; location near the posterior abdominal wall, close to the aorta and hence, aortic pulsation; little or no mobility, but in some places the influence of the respiration on the pancreas was visible, and the position of the artificially inflated stomach and the transverse colon, in front of the tumor. Seefisch has collected 149 published cases, of which 19 were treated by total and 12 by partial extirpation. In 118 cases the cyst wall was sutured to the abdominal wound, opened and drained.

Muenchener Med. Wochenschrift, June 4.

The Present Mortality After Gall-Stone Operations. H. Kehr.—Reviewing his 585 operations for gall-stones, Kehr observes that the mortality—aside from the cases complicated with carcinoma or diffuse cholangitis—is 3.7 per cent. in all, and only 1.7 per cent. in his last 60 operations. If the pancreas is involved—and the more he operates, the more frequently he finds acute or chronic inflammations of this organ—the prognosis depends on the possibility of curing the pancreatic affection. He attributes the improvement in his results of late years to his method of leaving the hepatic duct open and merely tamponing. He mentions that in his last 100 operations, 40 per cent. of the men died and only 8 per cent. of the women. Carcinoma of the head of the pancreas, and peritonitis with adhesions, are more frequent in men; probably both are due to traumatic influences from which women are exempt. As a general thing, he finds that women bear laparotomy better than men. Scheuer has calculated that about 41.5 per cent. of the cases are cured by internal treatment, Naunyn estimates the number at 40 per cent., and Furbringer has recently stated that about 50 per cent. of the patients leave Carlsbad uncured. Surgeons, on the other hand, cure 95 to 98 per cent. of all the cases that come into their hands, and an experienced surgeon is a much better expert at diagnosis than the best practitioner, as the latter seldom or never profits by that wonderfully instructive textbook, the surgical dissection *in vivo*.

Prager Med. Wochenschrift, May 2.

Neoplastic Thrombosis. C. Springer.—A sarcoma in the thyroid gland required tracheotomy, and neoplastic thrombosis was then noticed in the veins of the region. The autopsy showed that the edema in the face, and later in the arms, corresponded to the progress of the venous thrombosis from the neck toward the center and thence laterally to the subclavian. A fragment of the tumor had even found its way into the right heart, causing a peculiar murmur.

Diabetes Mellitus Simulating Gastrointestinal Affections. E. Schuetz.—In all chronic gastrointestinal affections from an unknown cause, the urine should be repeatedly examined for sugar. Diabetes frequently manifests itself first under the clinical picture of dyspeptic symptoms, gastralgia, colic or the gastric crises of tabes. These disturbances are usually accompanied by frequent neuralgias and paresthesia in various parts of the body, occurring simultaneously or alternately. Antidiabetic diet favorably modifies these disturbances.

Mechanism of Arsenical Treatment of Malignant Tumors. C. Trunecek.—The benefits of the application of arsenious acid in the treatment of epitheliomata of the face, are now established beyond further question. The Journal has frequently commented on and described the author's method. He now announces that carcinoma or sarcoma cells are directly necrosed by the action of the arsenic and their protoplasm coagulated. The stroma cells become degenerated and exudation follows, which in turn produces further changes in the tumor cells. Inflammation with demarcation is the result of the application of arsenic to the surrounding sound tissue. It gradually passes into a suppurative stage, terminating in the throwing off of the entire necrosed tumor as a foreign body. In short, the organism reacts to the arsenically treated tumor as to a foreign body and throws it off. The tumor left alone does not induce any reaction of this nature; the organism makes no effort to defend itself against it, and is in turn destroyed by it.

Sammlung Klin. Vortraege, No. 297.

Diagnosis of Puerperal Fever. P. Junge.—The difficulties of differentiating puerperal fever are peculiarly great when typhoid fever makes its first appearance at childbirth. Junge has had an experience of 2 cases of typhoid deceptively simulating puerperal fever, 6 of mastitis, 2 of acute arthritis, 1 of pharyngitis with a dermatitis and nephritis, and 1 of infarction of the lungs.

Wiener Klinische Rundschau, June 2.

Treatment of Bacteriuria. W. Buttermilch.—In most cases of bacteriuria a preceding intestinal affection will be noted. The bacteria invade the bladder through the blood and the treatment depends on whether their presence in the bladder is favored by some local lesion or not. In one case described the treatment was directed against the helminthiasis observed, followed by .5 salol four times a day. After five days this treatment was substituted by a 5 per cent. decoction of uva ursi leaves, a teaspoonful every hour. The urine was entirely clear in three weeks. In another case with gonorrheal antecedents, the bacteriuria resisted all the usual measures for four weeks, including large doses of camphor, but yielded at once to local irrigations with a 1 to 10,000 solution of sublimate. The colon bacillus was found pure in each case. The irrigations had to be repeated four times, as the bacteria evidently developed unchecked in the intervals of treatment, before their final annihilation. In the first case catheterization showed that the infection was by way of the kidneys and consequently general treatment was indicated. The blood was sterile at the time of examination in each case.

June 9.

Idiopathic Peritonitis. H. Nothnagel.—The enormous absorbing power of the peritoneum enables it to dispose of bacteria and toxins circulating in the blood and hence the peritoneum is not involved so frequently as the other serous membranes in case of acute infectious diseases, and there is no possibility of a primary, idiopathic inflammation. Rabbits can absorb without injury 3 to 8 per cent. of their weight of physiologic salt solution injected into the peritoneum. But in case of an affection in the vicinity of the peritoneum, the germs and toxins arriving in such large numbers, are liable to cause inflammation. Nothnagel denies that peritonitis can occur as a primary infection. He always traces it to some lesion in the vicinity: a catarrhal condition or laceration of the intestines, possibly some minimal traumatic lesion, allowing the passage of bacteria into the peritoneum. The only way in which microbes can reach the peritoneum in numbers sufficient to set up an inflammation, without solution of continuity, and the passage through some other tissue, is by way of the female genitalia. But in every case of the kind reported there has always been a co-incident genital affection, some focus in the vicinity from which the infection was propagated.

Wiener Klin. Wochenschrift, June 6.

Cerebral Abscesses in Connection with Affections of the Bronchial Lymph Glands. F. Schlagenhaufer.—At the autopsies of three young women who had died after an acute illness of four to six days' duration, suggesting suppurative meningitis, occurring in the midst of health, multiple abscesses were found in the brain. In two cases perforation had induced a suppurative meningitis. In each case the primary focus was discovered in a suppurating lymph gland below the bifurcation of the trachea, near the right bronchus. The bronchial gland abscess communicated either with the bronchus or esophagus or with both. The primary abscess was tubercular in each case; in two there were slight pulmonary tubercular lesions; in one the lungs were sound. Two similar cases of cerebral abscess have been reported, and the five suggest an explanation for the so-called idiopathic cerebral abscesses or cryptogenetic septicopyemia. The bronchial and tracheal lymph glands should be investigated in all such cases. They also confirm Ribbert's theory that the primary localization of pulmonary tuberculosis is not the lungs but the bronchial, peritracheal glands.

Wiener Med. Wochenschrift, April 13.

Early Diagnosis of Tabes and Paralysis. J. Donath.—A disturbance in the innervation of the iris muscles is indicated when the edges of the pupils are irregular; oval, pear-shaped, triangular or polygonal with rounded angles or picket-shaped. These irregularities in the edges of the pupils can be seen best in a dark room by lamplight, viewed from the side, with a powerful magnifying glass. Donath considers them pathognomonic of a pre-ataxic stage, which may or may not develop into progressive paralysis or tabes. He describes one case in which complete paralysis of the sphincter of the iris and the ciliary muscles preceded by ten years the manifestations of progressive paralysis. The ocular paralysis subsided after a few months. Five years later the pupil reflex vanished on both sides and after a similar interval symptoms of paralysis developed, fatal in six months, the patient previously robust and successful in extensive financial affairs. In another case, myosis, absence of the pupil reflex, and slight atrophy of the optic nerve have persisted for fifteen years, with no apparent tendency to further symptoms. The age assists in differentiating paralysis, as it usually appears between the thirtieth and fiftieth year.

Brazil-Medico (Rio de Janeiro), May 8.

Tropa-Cocain in Spinal Analgesia. D. de Almeida.—The writer reports a series of major operations successfully performed under spinal cocainization with a 2 per cent. solution of tropa-cocain. No mydriasis, headache nor vomiting was observed in any case.

Curare. J. B. De Lacerda.—The organizers of the recent Latin-American Congress invited Lacerda, the author of the theory of the symbiosis of the yellow fever germ with a mould, to deliver an address on the bacteriology of yellow fever. He refused, as his convictions on the subject have weakened of late and he did not feel himself competent to see clearly in the chaos at present reigning in regard to the etiology of the disease. He reported instead, some recent research on the subject of curare, which he discovered is made by the Ticunas from a mixture of plants, including Castel Ney Strychnos, a piperacea and the anomospermum grandifolia. Studying the latter alone, he found that the fluid extract possessed all the properties of curare. The progress of the paralytic phenomena is more clearly defined than even with curare, showing the succession of the symptoms, commencing with paralysis of the hind legs, then of the forelegs, muscles of the tail, ears, lids and finally of the respiratory muscles. The sensory perceptions are retained to the last.

Revista Medica de Bogota, Colombia, No. 250.

Yellow Fever. N. Osorio.—A suspicious fever is epidemic at certain points in Colombia and Osorio appeals to the authorities to appropriate funds for the manufacture of Sanarelli's anti-yellow-fever serum, which he considers the only effective remedy to date against the disease.

Yellow Fever. J. M. Escobar.—The writer's long experience with yellow fever shows that the best results are attained by the following treatment: Against the fever, cold baths and iced, acid drinks are sufficient. The same drinks are indicated in case of vomiting, alternated with small glasses of champagne mixed with equal parts of an alkaline water. If these fail, he prescribes five drops of essential oil of cajeput in an aromatic infusion, supplemented by ether or chloroform, but never by cocain. A milk diet and alkaline drinks are the best means to sustain the renal permeability, but when the amount of albumin exceeds 1.5 per 1000, the urinary insufficiency requires more immediate measures, and oxygen inhalations are indicated. In one case the albumin attained 3.5 per 1000, but had entirely vanished after four days during which twenty-four liters of oxygen had been inhaled each day. In case of hemorrhage, besides the usual hemostatic measures he administers calcium chlorid, as the change in the blood plasm is the immediate cause of the multiple hemorrhages; continuing the oxygen, which has proved so successful in hemorrhage consecutive to icterus. The diet should be restricted to coffee, champagne and milk containing an alkali, but if rectal alimentation alone is possible, water should be given copiously, brandy to stimulate the circulation and peptonized milk. Papain is preferable to pepsin for the purpose, however, as it works in an alkaline medium while the latter requires an acid.

Queries and Minor Notes.

LODGE PRACTICE.

Ashton, R. I., June 14, 1901.

To the Editor:—By enclosed clippings from the Pawtucket, R. I., *Times* of 13th inst., you will perceive how the profession is degraded by men who allow themselves to be championed and exploited, we might say enslaved, by secret and other societies in opposition to ethical members of the profession, who are consequently insulted by municipal bodies daring to offer them a miserable dime-piece for their services, which was, no doubt, greedily clutched at.

The Medical Association of Pawtucket, numbering among its members the leaders of the profession in that city, refused to meet with those who eagerly grasped at the miserable pittances forced on them by the secret and other societies, and who have banded themselves in a rival club named the Pawtucket Medical Society, which is, I need not say, not affiliated with the State Society. Some of them come out here, a distance of five miles, to examine for an Insurance Company which flings to them the munificent dole of 25 cents per capita, as you would a bone to a dog. Comment is unnecessary.

Following is the clipping referred to: "The meeting of Court City of Pawtucket, Foresters of America, which was held last evening in St. George's Hall, Cole's Block, was of more than ordinary interest because a movement was begun to institute a boycott of the physicians of the city and vicinity who are members of the Pawtucket Medical Association, because of the stand taken by the association that no member of the association can act as physician for any lodge or social, secret or fraternal organization within the jurisdiction of the association, unless in violation of the ethics of the fraternity. It will be recalled that recently the Pawtucket Medical Association declared against any member acting as lodge physician, and this fact in due time came to the attention of the court. Last night the subject was well discussed and action was taken after the subject had been pretty well talked over and well understood. It was voted to appoint a committee of three to confer with all social, fraternal and secret organizations of Pawtucket and vicinity for the purpose of securing the united pledging of the support of the various organizations, in a movement that shall pledge every member of the lodges and societies not to employ for himself or family a member of the Pawtucket Medical Association. There was a great deal of plain talk, and it was held by some of the speakers that the stand of the association was arbitrary and there were just as good physicians out of the association as were included in the membership. The committee was authorized to act on its own discretion, but to lose no time in carrying out the instructions, which were given by unanimous vote of the court."

N. O'D. Parks, M.D.

Ans.—We know nothing further of the merits of this particular case, but that physicians in many places are being used by organizations for the aggrandizement of these bodies is well known. It would be well if this growing evil could be recognized before it is too late and if it could be met by an organized profession, and not by a disorganized one, as seems to be the case in Pawtucket.

THE HIPPOCRATIC OATH.

Ithaca, N. Y., June, 1901.

To the Editor:—Will you kindly send me a copy of the Hippocratic oath, or tell me where I can get one? A. T. K.

THE OATH.

I swear, by Apollo the physician, and Æsculapius, and Health, and All-heal and all the gods and goddesses, that, according to my ability and judgment, I will keep this oath and this stipulation to reckon him who taught me this Art equally dear to me as my parents, to share my substance with him, and relieve his necessities if required, to look upon his offspring in the same footing as my own brothers and to teach them this Art, if they shall wish to learn it, without fee or stipulation, and that by precept, lecture and every other mode of instruction, I will impart a knowledge of the Art to my own sons and those of my teachers, and to disciples bound by stipulation and oath, according to the law of medicine, but to none others. I will follow the system of regimen which, according to my ability and judgment, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to any one if asked, nor suggest any such counsel; and in like manner I will not give to a woman a pessary to produce abortion. With purity and with holiness I will pass my life and practice my Art. I will not cut persons laboring under the stone, but will leave this to be done by men who are practitioners of this work. Into whatever houses I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption; and further from the seduction of females or males, of freemen and slaves. Whatever in connection with my professional practice or not in connection with it, I see or hear, in the life of men, which ought not to be spoken of abroad, I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this Oath unviolated, may it be granted to me to enjoy life and the practice of the Art respected by all men in all times!

But should I trespass and violate this Oath, may the reverse be my lot!

CONGENITAL NASAL DEFORMITY.

MINNEAPOLIS, MINN., May 27, 1901.

To the Editor:—I have a patient whose face is rather disfigured by a congenital deformity of the nose, to remedy which it would be necessary to increase the height of the septum. Please tell me if such operations have proven successful and give the address of some surgeon making such operations a specialty, to whom I could refer this patient with assurance of fair treatment.

Yours truly, A. B. C.

ANS.—Such operations are being successfully performed almost daily, and the results are usually satisfactory. Each case is peculiar to itself, and just what will have to be done can only be determined by examination of the particular case. We can not recommend any particular surgeon. As it is not a specialty, all well-qualified surgeons are prepared to operate on such cases.

RHODE ISLAND STATE BOARD.

RICHMOND, VT., June 13, 1901.

To the Editor:—Please give me the name and address of the secretary of the State Board of Medical Examiners of Rhode Island.

W. T. T.

ANS.—Address Dr. Gardner T. Swarts, Secretary State Board of Health, 48 Weybosset St., Providence, R. I.

STATE BOARD EXAMINATIONS.

CARROLLTON, KY., June 17, 1901.

To the Editor:—Please give me list of states in which a graduate of a recognized medical college can practice without having to stand the state board examinations. J. H. A.

ANS.—The answer to this query appeared in THE JOURNAL of April 13, p. 1081.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., June 13 to 19, 1901, inclusive:

Lawrence C. Carr, major and surgeon, Vols., recently appointed, relieved from duty in the Department of Cuba, when his services can be spared by the general commanding that department, to proceed to San Francisco, Cal., en route for assignment to duty in the Division of the Philippines.

Henry R. Carter, Jr., contract surgeon, former orders so amended as to direct him to proceed to his home, New Orleans, La., for annulment of contract.

J. C. Garlington, contract surgeon, leave of absence granted.

Frederick C. Jackson, captain and asst.-surgeon, Vols., from temporary duty at Columbus Barracks, Ohio, to San Francisco, Cal., en route to duty in the Division of the Philippines.

Frank R. Keefer, captain and asst.-surgeon. U. S. A., leave of absence granted.

Franklin M. Kemp, lieutenant and asst.-surgeon, U. S. A., from West Point, N. Y., to San Francisco, Cal., en route to duty in the Division of the Philippines.

William L. Kneedler, major and surgeon, U. S. A., now under treatment at the U. S. General Hospital, Presidio of San Francisco, Cal., relieved from further duty in the Division of the Philippines, to proceed, on the expiration of his present sick leave, to West Point, N. Y., to relieve Lieut. Franklin M. Kemp, asst.-surgeon, U. S. A.

Stanley S. Warren, contract surgeon, from Fort Clark, Tex., to his home, Shelbyville, Tenn., for annulment of contract.

William P. Woodall, contract surgeon, from Salado to Fort Clark, Texas.

In addition to the above the following-named officers are detailed as members of the faculty of the Army Medical School: Colonel Wm. H. Forwood, asst. surgeon-general, U. S. A., as president of the faculty, vice Colonel C. H. Alden, U. S. A., retired; Colonel Calvin DeWitt, asst. surgeon-general, as professor of military medicine; Maj. John Van R. Hoff, surgeon, as lecturer on the duties of medical officers in war and peace; Major William C. Borden, surgeon, as professor of military surgery, vice Colonel Forwood, designated as president of the faculty; Major William P. Reynolds, surgeon. U. S. Vols. (captain and asst.-surgeon, U. S. A.), as instructor in Hospital Corps drill and first-aid to wounded, vice captain George D. DeShon, relieved.

Navy Changes.

Changes in the Medical Corps of the Navy, week ended June 22, 1901:

Dr. H. M. Tolfree, appointed assistant-surgeon from June 14, 1901.

Surgeon C. F. Stokes, ordered to the *Solace,* upon arrival in the United States.

Asst.-Surgeon R. B. Williams, ordered to the *Kearsarge,* June 24.

Asst.-Surgeon F. M. Furlong, detached from duty at Guam and ordered to the *Solace* for transportation home.

Asst.-Surgeon R. K. McClanahan, detached from the *Culgoa* and ordered to the *Vicksburg.*

Asst.-Surgeon D. B. Kerr, detached from the *Vicksburg* and ordered to the *Culgoa* to wait orders en route

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended June 20, 1901:

Surgeon C. T. Peckham, granted extension of leave of absence, on account of sickness, for thirty days from June 20.

Surgeon R. M. Woodward granted extension of leave of absence for three weeks from June 5.

P. A. Surgeon C. H. Gardner, granted leave of absence for seven days from June 21.

Asst.-Surgeon G. M. Corput, relieved from duty at the port of St. Louis, Mo. Leave of absence for one month granted by bureau telegram of May 16, amended so that said leave shall be for twenty-one days only.

Asst.-Surgeon Dunlop Moore, to proceed to Port Townsend, Wash., and assume temporary charge of service during absence of P. A. Surgeon C. H. Gardner.

A. A. Surgeon B. J. Brown, Jr., granted leave of absence for fourteen days from June 20.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for two days.

Hospital Steward W. F. Schlaar, relieved from duty in the Hygienic Laboratory, and directed to proceed to Key West, Fla., and report to the medical officer in command for duty and assignment to quarters.

Hospital Steward E. B. Scott, granted leave of absence for twelve days from June 24.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended June 22, 1901:

SMALLPOX—UNITED STATES AND INSULAR.

California: San Francisco, June 2-9, 1 case.

Florida: Key West, June 5, 1 case.

Illinois: Chicago, June 8-15, 4 cases.

Indiana: Evansville, June 8-15, 1 case; Michigan City, June 10-17, 2 cases; South Bend, June 8-15, 1 case.

Iowa: Clinton, June 8-15, 1 case.

Kansas: Wichita, June 8-15, 3 cases.

Kentucky: Lexington, June 8-15, 1 case.

Louisiana: New Orleans, June 8-15, 11 cases.

Massachusetts: June 8-15, Fall River, 1 case; New Bedford, 3 deaths; Worcester, 8 cases, 2 deaths.

Michigan: Detroit, June 8-15, 33 cases, 1 death; Sault Ste. Marie, June 16, prevalent.

Minnesota: Minneapolis, June 8-16, 17 cases; Winona, June 8-15, 1 case.

Missouri: St. Louis, June 2-9, 37 cases, 1 death.

Nebraska: Omaha, June 8-15, 12 cases.

New Hampshire: Manchester, June 8-15, 6 cases.

New Jersey: Jersey City, June 8-16, 2 cases; Newark, June 8-15, 3 cases; Plainfield, June 8-15, 1 case.

New York: New York, June 8-15, 102 cases, 11 deaths; Yonkers, June 7-14, 5 cases.

Ohio: Cincinnati, June 7-14, 5 cases; Cleveland, June 1-15, 45 cases; Dayton, June 8-15, 1 case; Toledo, June 8-15, 1 case.

Oregon: Portland, May 1-June 5, 23 cases.

Pennsylvania: Philadelphia, June 8-15, 3 cases, 1 death; Pittsburg, June 8-15, 2 cases.

Rhode Island: Providence, June 8-15, 3 cases.

Tennessee: Memphis, June 1-15, 26 cases, 2 deaths; Nashville, June 8-15, 1 case.

Utah: Salt Lake City, June 8-15, 8 cases.

Vermont: Rutland, June 8-15, 1 case.

Washington: Hoquiam, June 10, 1 case.

West Virginia: Wheeling, June 8-15, 1 case.

Wisconsin: Green Bay, June 8-16, 6 cases; Milwaukee, June 8-15, 3 cases, 1 death.

Philippines: Manila, April 20-May 11, 18 cases.

SMALLPOX—FOREIGN.

Austria: Prague, May 25-June 1, 4 cases.

Belgium: Antwerp, May 25-June 1, 2 cases.

Ceylon: Colombo, May 4-11, 5 deaths.

China: Hongkong, April 26-May 11, 5 cases, 2 deaths.

Colombia: Panama, June 3-10, 6 cases.

France: Paris, May 25-June 1, 10 deaths.

Gibraltar: May 24-June 2, 1 case.

Great Britain: Glasgow, June 1-7, 35 cases, 1 death; Liverpool, May 25, June 1, 2 cases; London, May 25-June 1, 1 case.

India: Bombay, May 14-21, 8 deaths; Calcutta, May 11-18, 31 deaths; Karachi, May 12-19, 4 cases, 2 deaths; Madras, May 4-17, 22 deaths.

Italy: Messina, May 25-June 1, 1 death; Naples, May 26-June 2, 169 cases, 30 deaths.

Russia: Moscow, May 18-25, 25 cases, 1 death; St. Petersburg, May 18-25, 15 cases; Warsaw, May 11-18, 4 deaths.

Spain: Corunna, May 25-June 1, 1 death.

Straits Settlements: Singapore, April 1-30, 3 deaths.

Switzerland: Geneva, May 18-25, 5 cases.

Syria: Beirut, May 18-25, a few cases.

YELLOW FEVER.

Cuba: Havana, June 1-8, 1 case.

CHOLERA.

India: Bombay, May 14-21, 3 deaths; Calcutta, May 11-18, 77 deaths; Madras, May 4-17, 6 deaths.

PLAGUE—INSULAR.

Philippines: Cavite, May 2, 1 case; Cebu, May 2, 1 case; Manila, April 20-May 11, 94 cases, 79 deaths; Santa Rosa, May 2, 1 case.

PLAGUE—FOREIGN.

Africa: Cape Town, May 4-18, 463 cases, 209 deaths.

China: Hongkong, April 27-May 11, 221 cases, 209 deaths.

India: Bombay, May 14-21, 224 deaths; *Calcutta,* May 11-18, 79 deaths; Karachi, May 12-19, 149 cases, 144 deaths.

Address.

SECTION ON PRACTICE OF MEDICINE.

ADDRESS OF CHAIRMAN DELIVERED AT THE FIFTY-SECOND ANNUAL MEETING OF THE A. M. A., HELD AT ST. PAUL, MINN., JUNE 4-7, 1901.

J. M. ANDERS, M.D., LL.D.
PHILADELPHIA.

Upon those selected to guide and direct the executive work of this large and important section of the American Medical Association, devolves a difficult task and a weighty responsibility. The high character and comprehensive scope of the work actually accomplished by the Section, more especially during the last two decades, is a forcible reminder that lack of concentrated effort in the future will result in stagnation, if not a backward step, instead of progress. You may be assured that with these thoughts ever in mind, those charged with the office work and the preparation of the present program spared no effort to make it attractive, interesting and meritorious. I desire here to make public acknowledgment of the efficient services so cheerfully and faithfully rendered by the Secretary of the Section.

It might seem befitting a chairman's address, at first sight, to take a retrospective view and consider the progress of internal medicine during the last 100 years, at this, the first meeting after the dawn of a new century in its nascent glory, but I join my predecessor, Dock, who says: "These things have been told and retold in more eloquent tongues."

The past is only useful as it furnishes inspiration for the present, hence, contrary to custom, generally speaking, my brief utterances shall not be reminiscent in character. To come down to the past year, it would indeed be hard to describe fully the fruits of that brief period. Moreover, this would be a work of supererogation, since you have already been made acquainted through the medical press with its most important advances and discoveries. Again, neither the number nor the relative importance of the published medical discoveries and fresh views can be arrived at by a process of induction while we are yet so close to the scene of action. Time is needful to encompass, confirm and properly appreciate the true worth of new scientific truths, as well as to determine precisely their range of practical application.

New truths are the raw material, which must be refined by a process, first of confirmatory investigation, then of practical application, before they become the finished fabric and constitute a part of the sum of, or mark an advance in, scientific knowledge. All this is necessary in order that nothing that is good shall be lost to mankind and nothing that is false shall fail to be rejected. Specific points connected with subjects in the developmental stage are likely to be considered by the essayists at these meetings and to be subsequently discussed by the members. Hence the folly of attempting to estimate or to delineate accurately the real or noteworthy and numerous minor improvements at the close of each year. This, however, can be accomplished with ease and certainty from the point of vantage of the future. On the other hand, I am not protesting against the propriety of allusion to revolutionizing and startling discoveries that are of universal interest and promise much for the future, in scientific addresses.

I am not rash enough to attempt a prophecy for the future of internal medicine—a tempting task—but cheered and encouraged by the unparalleled leaps and bounds of the last two decades, we turn with hope and confidence to the new, with its boundless opportunities and possibilities.

It has been questioned by some whether we may hope to make a "proportionate advance in the future," as compared with the course of events in the recent past, but the marvellous expansion of laboratory research, and the greater precision in methods of clinical observation, leave little room for doubt that the increase in actual knowledge will be at an increased ratio—there will probably be witnessed a new era of scientific achievement. At all events, we may anticipate greater progress in the coming years, unless, perchance, the profession falls short in the matter of training the senses and of cultivating critical judgment. Here may be thrown out a word of caution, lest the predominant tendency of the day to rest confidently upon the results of the refined, scientific methods of investigating disease lead to the unconscious neglect of careful bedside observation. The most fruitful results have been and ever will be attained when personal observation and the more exact laboratory methods are happily combined. The medical horoscope, however, reveals nothing that is calculated to inspire universal uneasiness and I have little patience with pessimistic views as we face a period that doubtless holds in store products and triumphs in original research and in practical experience and observation that we will not have dreamed of.

At present this body enjoys the cordial support and sympathy of the majority of the leading medical men throughout the country. It has met the necessities of the past and it will well meet the requirements of the future. The rapid growth and ever-increasing importance of the Section emphasizes the conspicuous ability of those who conducted its scientific business during the recent past. On searching the records of by-gone days, one may discover counsels of their wisdom for future guidance and action; and yet not to be overlooked is the fact that what was best or even good then may not be so now, so radically do conditions change within brief periods, in consequence of the rapid progress of medical science.

The medical section of the American Medical Association can point without ostentation and with becoming modesty to its record; it has accomplished highly creditable pieces of scientific work, but its rise and growth can not continue indefinitely unless those most deeply interested in its success and intrusted from time to time with the unenviable responsibility of formulating and executing plans for larger usefulness, give even more laborious and careful attention to the arrangement of subjects, the selection of essayists of wide reputation, the office work and other details in the future than in the past. This is necessary if the utility of the work accomplished by our Section is to be commensurate with, or to keep pace with, the development of our science. It is to be recollected that as it assumes a more and more conspicuous or commanding position among professional organizations, the greater will be the danger from deterioration or disintegration. Indeed, "the safety of any organized body is in inverse ratio to its size" (Rothrock), or, in other words, so soon as it commands attention and stirs the thought of the general public, it invites honest criticism. This is no new idea, but a well-established physical law. Hence, although there are no "vague shapes of gloom" in the horizon, it behooves the conductors of the offices of this organization to keep in remembrance the principles it embodies and to adopt a policy that will at all times reflect, what after the closest scrutiny, observation, experience, investigation and honest conviction is believed to be the highest wisdom and calculated to promote the highest interests of the Section. This policy should, it seems to me, determine also what subjects shall be discussed and whether certain questions are of sufficient importance to be discussed at all. The effect and the object aimed at would be probably to lessen the number of topics considered at each session, but it would give impetus to the merits of the papers presented and would also allow more time for their discussion. Nothing is gained by presenting an overfilled program that can neither be carried out satisfactorily nor enjoyed by the members. The amount, as well as the character, of the material supplied should be prearranged with greater care than is practicable under the present system, so that the proceedings could be grasped within the time allotted to our sessions. Symposia meet the difficulty to a certain extent, particularly if previously arranged and planned in such a manner as to avoid repetition, as well as to present the most interesting aspects only of the subjects brought forward. It is my firm conviction that the growth of the medical section and its influence upon the medical profession of the United States could be greatly enhanced by extending the work of the Executive Committee. Better still, perhaps, would be the appointment of a special committee on scientific business. This committee should hold office for from three to five years, thus insuring a membership conversant with the working arrangements and needs of the Section. The Secretary of the Section should be a member of this committee and the chairman a member ex-officio. All papers intended for presentation at the annual meeting of the Section should be in the hands of and scrutinized by the committee at least one month prior to the date of the meeting.* A part of the function of the special committee previously suggested should be to report plans, and broadly sketch new features with a view to effecting improvements in the work, thus insuring the greater prosperity of the Section for the future and removing certain deficiencies that may tend to limit its utility. I care naught whether the suggestions I have ventured be adopted, but I do affirm that the times are ever ripe for readjustments looking to the improvement and betterment of the character of section work. I desire to invite especial attention to the timeliness of a self-examination, a close scrutiny of the internal condition of things.

I am pleading for a policy that will tend to exalt the professional importance of the Section, which should at all times be specially representative of the best medical research as well as the ripest experience and observation of this fair land; and for a policy that shall insist upon a maximum of creative, constructive, original work to the exclusion of wearisome individual details and cumbersome bibliography. These meetings should be the occasion of the most important contributions to *practical* medicine.

Assuming this position to be incontrovertible, are we thoroughly alive to our responsibilities and opportunities? My apology for raising this query, if any is needed, is that one meets with comments like the following[1]: "The meeting itself appears to have been one of interest. The papers read were not of very striking originality. Perhaps we should except two of them from this remark." When it is recollected that these statements apply to the meeting of the American Medical Association in general, and that the total number of papers read before this body annually is several hundred, the words quoted above can not be regarded as a gratifying expression of approbation.

The accomplishment of high praise instead of comments like the above is the goal for this organization. If it be thought from these remarks that my attitude is too pessimistic, I must demur; on the other hand, I affirm that the times and the occasion are alike pregnant with promise and encouragement. Conditions are most favorable when viewed in the light of the situation as it existed in the recent past. My sole desire is to emphasize the importance of carefully watching and guarding the Section in its upward movement. Surely the auspicious opening of a new century should furnish a hopeful prospect and mark another mile-stone in its march toward an era of increased prosperity and greater practical utility.

Specialism in the science and art of medicine is an absolute necessity, but I venture to suggest that certain reforms are desirable in the line of rearrangement of the work that has been embraced under the Section on Practice of Medicine, as well as in those most closely allied to it. I am, and have been, in thorough accord with the establishment of the Section on Pathology. This is a special department of medical science for those who take a really scientific interest in the subject, and those who have had careful training in the methods of investigating the more obscure and finer questions in morbid anatomy and pathology. The technical knowledge that results from these laboratory studies, and the expert opinions based upon them, however, are of no small value in the study and recognition of many diseases. We welcome the fruits of these labors and utilize them, but the majority of the members of the medical section have neither the training nor the time needful to devote to the detailed work of the new Section. On the other hand, the general practitioner must constantly keep before the mind's eye a picture of the gross lesions of disease, and must appreciate the processes involved in their pathogenesis in order that the clinical manifestations may be properly appreciated. The lines between the sections on medicine and pathology, however, should never be too closely drawn. There is a narrow border field in which clinical observation, laboratory investigation and postmortem findings are inseparably associated.

---

* These suggestions are met in part by the new rule compelling the retiring chairman and two members of the Executive Committee to approve all papers presented before the Section before they can be published in The Journal, but does not prevent the reading of unworthy articles.

[1] Editorial in The Lancet, London, vol. ii, 1893.

In the case of the Section on Materia Medica, Pharmacy and Therapeutics, we have an instance in which cleavage has been overdone; and it is recognized by many who have been closely identified with that section that, so far as applied therapeutics is concerned, it is of practical interest and importance exclusively to the clinician. The greatest progress in internal medicine has been, during the last century, in the sphere of diagnosis, while the advance in applied therapeutics has been comparatively slight. It is true that we are experiencing a wave of over-activity relative to the number of novel remedies brought to the attention of the medical profession, but trustworthy records or positive statements concerning the majority of these are sadly wanting. Indeed, a note of warning against the injudicious employment of novel remedial agencies is timely at present. Their action, or supposed action, upon the human economy does not in many cases rest upon the results of experimental pharmacology, but, as a rule, simply upon the briefly summarized personal experience of a single practitioner, whose promulgated statements serve as the basis of a catching and alluring advertisement for some enterprising firm with, let us charitably hope, the most laudable intentions.

Much to be deplored are the hidden purposes of our professional brethren who vaunt novel agents without even presuming to afford clear and convincing evidence of their therapeutic value. It is, however, to be looked upon as a favorable indication that an awakening on the part of the profession at large to the importance of greater interest and attention to the all-important subject of the restoration of health to the sick, and even to the symptomatic treatment of disease, is taking place. The prime object of our art is to cure disease. What manner of physician is he who fails to exert strenuously the resources of that art? Surely none of us would be willing, after making a precise and careful diagnosis in a given case, to step aside and allow the therapist to conduct the treatment. Nor should we, as clinicians, feel gratified to continue in attendance upon a case in which the treatment was dictated by a specially-trained therapeutist. This granted, obvious harm has arisen and will doubtless continue to arise from injudicious specialism. It is true that the study of the physiologic action of drugs is the basis of scientific therapeutics; it is equally true that the progressive clinician must avail himself of such knowledge—the finished laboratory product—resting as it does on the immutable basis of physical truth. As practitioners, however, we know that while there is a therapeutics founded upon pharmacology, thanks to the genius and labors of Magendie and Bichat, there is also an empiric therapeutics and a yet wider sphere of curative action in hygienic means, including dietetics. Whatever forces are of practical use must be embraced in the armamentarium of the medical practitioner; he must know the proper basis for their application, and the fundamental laws or rules that serve as guides to the attainment of scientific accuracy in his efforts to overcome disease.

Among the important questions pertaining to the treatment of disease that are awaiting a clearer solution and should be considered by this Section may be mentioned; serumtherapy, organotherapy, the higher precision of results from alkaloids as compared with crude drugs, the true sphere of hydrotherapy, of climate, rest, exercise, massage, diet, venesection, and electricity. Would not a more careful, thorough and comprehensive consideration and a fuller informal discussion of these subjects by the Section lead to increased knowledge pertaining to most valuable aids for the relief of suffering and the cure of human ills? Is not the oft demonstrated fact that medicines are the least important part of the treatment of disease too commonly lost sight of by essayists? For example, success in the treatment of disease is often possible only by the use of appropriate dietetic measures. "The father of medicine," Hippocrates, was fully alive to the importance of a wise selection of pabulum for the sick. Knowledge of the fundamental principles of dietetics is essential for the conducting of the cure of disease (Clarke). Too little interest is manifested by the general practitioner in the diet treatment of disease; he is in great need of practical information relating to this theme and of enlightened discussion of the subject. Now, there could be no more opportune time than the present and no more appropriate place than in this section to consider and discuss this subject in its practical phases; and the same remark would apply to the other physical methods of treatment to which I have made passing reference.

The development of proper and efficient systems of treatment must be the achievement of the physician; he must master their "spirit and form," for he alone is acquainted with the complexity of the indications calling for their utilization. I have been surprised that an upheaval of sentiment in favor of a return to first principles, or a throwing of therapeutics where it properly belongs, into the Section on Practice of Medicine, has been so long delayed. I am not protesting against a special section, properly organized for the prosecution of certain definite lines of investigation, more particularly the physiologic action of drugs, their constitution, and materia medica proper—a section of "Pharmacology, Pharmacy and Materia Medica," if you will pardon a suggestion. As in the case of morbid anatomy and pathology, the clinician is interested in the results of such scientific work; the accurate knowledge thus gained by the laboratory experimentalist is of marked value to the successful treatment of disease and satisfactory observation at the bedside.

I am not an advocate of the unlimited multiplication of sections, and I have a fixed belief that the best method of making the AMERICAN MEDICAL ASSOCIATION the aggressive, energetic and world-famed organization that all of its members must wish it to be, is by a co-operation of the more or less closely allied sections in the bringing forward and the discussion of certain subjects or selected aspects of appropriate themes that possess leading interest, in joint sessions.

I am led in consequence of these reflections to make another step in the same direction, and refer briefly to the brilliant dawn of a new morning on which the obscuring mists of ignorance, prejudice and misconception have been lifted by the light of advancing truth, and the gifts of surgery to medicine are appreciated and cordially welcomed. The increasingly large number of human ills in which surgical aid is invoked suggests the thought that a closer affiliation of the surgical and medical workers would be of importance to the welfare of mankind.

Speaking of specialism, says Shattuck,[2] "The heais practically the only viscus which remains the exclusive property of the physician, and I am not so sure that even this organ will soon be attacked and we may hear of suturing mitral valves." Of a truth, this organ has been invaded by the surgeon. Neither the physician nor the surgeon can afford to confine himself alone to his specialistic studies; there should be held more frequent meetings on a common platform for the discussion of certain subjects or phases of topics of mutual interest; and consultations in the operating theater and at the bedside, as well as combined medical and surgical clinics in the arena for the benefit and instruction of students are urgently demanded. Truth and fairness compel the admission that the zealous surgeon is sometimes more to be honored, possibly even rewarded, for what he attempts than for what he actually achieves. Without wishing to detract from the merits of our surgical confrères, the medical practitioner is compelled to witness or learns of surgical operations having been performed which would most probably not have been executed had the operator first consulted with a progressive clinician. Conversely, the physician would grow less conservative as the result of more frequent consultations between himself and surgeons—a consummation to be desired. The thyroid gland has been extirpated *in toto* for exophthalmic goiter with resulting myxedema; cholecystotomy has been performed too commonly for supposed cholelithiasis where gall-stones were not in evidence after opening the abdominal cavity. These conditions, and numerous others that could be cited, should be carefully and thoroughly studied by both physician and surgeon, prior to operating, in order to determine precisely the nature of the affection in the case and the indications for treatment, medical and surgical. If this suggestion be not more generally adopted in the future than in the recent past, there remains but a single course open to the medical man, namely, to enter the domain of surgery.

---

[2] Address in Medicine, Phila. Med. Jour., Sept. 22, 1900.

In short, somehow or other, the medical man and the surgeon should be brought into closer, truer and more intimate relations with one another along certain definite lines, in the growing border lands, so to speak, between *internal medicine* and surgery. This is essential to the attainment of the true dignity, the comprehensive scope and beneficent intent of the medical profession. The morbid processes that we term medical diseases are not entities, and this is equally true of surgical conditions and affections; and success in the matter of their treatment demands, in many case, the combined efforts of the physician and the surgeon. Analogously, while each section of the American Medical Association has, for the most part, a distinct function (and while the best work may be done by the special local and national societies), yet the judicious affiliation of those sections having interests in common is indispensable to the realization of the full measure of our strength and our influence as a national organization. No greater stride toward the attainment and maintenance of our true position, toward promoting professional achievement and welfare or strengthening the pillars of the Association could be taken than by a closer, truer union wherever the strands of mutual interest of the different sections are inseparably interwoven.

Finally, if the American Medical Association hopes to be one of the great powers of the country, it is of grave importance that the proposed reorganization scheme be promptly effected and that due effort be made to establish and maintain proper respect and forbearance between the various sections, to the end that they may work in perfect harmony with one another.

I have attempted to point out a few lines on which our organizational and professional progress must be conducted. If I have seemed to lay too much emphasis upon the interdependence of certain sections of the Association and insufficient stress upon scientific investigation and data as the one sure means to a desired end, I would say in extenuation that the apparent omission is to be ascribed to the restrictive custom as to the time for a chairman's address. On the contrary, in the special work of this section, or any of the others, contributions based on original obesrvation and research must, in the future as in the past, constitute the choicest fruitage. Looking to the attainment of these higher results, permit me to suggest, in concluding, that an earnest effort should be made to enroll on the escutcheon of our Section all the master spirits in America, all who are bound together by the common tie of special research and observation in the broad field of internal medicine.

Original Articles.

APPENDICITIS.*

JOHN B. DEAVER, M.D.
PHILADELPHIA.

In addressing the medical section at this meeting, I acknowledge to a feeling of great satisfaction, for though my subject is a surgical one, I can come before you without hesitation, since no one has such power to increase the application of surgery as the general practitioner—not by diagnosis alone, but even more by a proper comprehension of these morbid conditions most commonly seen by the surgeon.

I shall make a few remarks on appendicitis, and though to some of you this may seem a topic sufficiently discussed, yet many false ideas still cling to it, and each day convinces me of the necessity of threshing out the matter until the priceless grains of truth remain.

The appendix is probably the most vulnerable of the abdominal organs, and this from several causes: 1. It is a structure in the process of retrograde metamorphosis; it is deficient in blood, nerve and lymphatic supply; it is long and its caliber is small, hence its drainage is easily interfered with; and lastly it is subjected to traumatism by the movements of the psoas muscle, on which it usually lies. From this, then, it is apparent that the appendix may easily become a very target for the destructive micro-organisms—normally present in its lumen—where from any cause these are incited into activity; and it is especially noteworthy that a hollow, glandular organ remains intact only so long as the production and evacuation of its secretion continues normally. When this function is deranged there are serious results: 1, retention, stagnation and decomposition of the appendix contents; 2, pressure, leading to impairment of the appendix wall; 3, and most important, the bacteria, especially the colon bacilli, are so increased in number and virulence that they are able to penetrate the coats of the appendix and set up their irritant processes in varying degrees. Such is, in brief, the pathogenesis of appendicitis—a complex process, essentially progressive in character.

In conformity with clinic observation two varieties of inflammation of the appendix are recognized, an acute and a chronic; and while a chronic appendicitis may be the result of a previous acute process, yet it must not be forgotten that appendicitis may also be chronic from its inception. The following classification is suggested as convenient and well founded. Acute appendicitis: 1, catarrhal; 2, interstitial; 3, ulcerative; 4, gangrenous. Chronic appendicitis: 1, catarrhal; 2, interstitial; 3, obliterating.

---

* Read in the Section on Practice of Medicine, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

It must, however, be frankly admitted that we are not always able to distinguish clinically the different pathologic varieties of appendicitis. Indeed, dissimilar lesions may even present identical symptoms; nor do the clinical manifestations bear any suitable proportion to the degree of involvement of the appendix.

These apparent inconsistencies are explained by the fact that most symptoms are due to peritoneal inflammation by extension, and nothing is more striking than the diverse reaction of the peritoneum to the same variety of inflammation as seen in different cases. In addition, the inflammatory phenomena are dependent on the situation and extent of the lesion, the rapidity of its progress and the changes induced by possible previous inflammation. The majority of appendical inflammations are chronic in nature; and many of the so-called acute cases represent exacerbations, a relighting of a quiescent focus, whose unsuspected presence an accurate history, I am sure, would often indicate.

It is not rare to have demonstrated in an individual the whole pathology of appendicitis, as when a chronic catarrhal appendicitis develops interstitial changes, ulcerates, becomes gangrenous and perforated, and is partially liquefied in an abscess; in chronic cases this sequence is common after months and years. But in the acute cases these same destructive effects are the rule, and take place with extraordinary rapidity, only requiring ten to twelve hours for the formation of a considerable pus collection or purulent peritonitis as adhesions determine. As in other diseases, so in this, nature makes an attempt at conservative resistance by adhesions to localize the inflammation and resulting abscess.

But I have never seen much good from these efforts of nature to cure; for the abscess itself, by its tendency to infect the peritoneum, is a grave menace, and even if the abscess ruptures into a hollow viscus, like the intestine or bladder, the situation is not much better. In this connection it seems advisable to refer to a variety of appendical inflammation which, not dangerous in itself, has been the indirect cause of innumerable deaths; I refer to obliterating appendicitis. Complete obliteration of the lumen of the appendix is the familiar standby of many general practitioners, but it is a will-o'-wisp; it does occur, I admit, but so rarely as to be practically non-existent, and in several thousand abdominal operations I have seen it scarcely a dozen times. The relation to treatment is obvious.

This, then, is a short sketch of certain features of the pathology of appendicitis, and two points in it I especially emphasize: 1. The practical non-existence of any form of inflammation which by obliterating its lumen renders the appendix harmless. 2. The appalling rapidity and suddenness with which the appendix may suffer bacterial invasion and necrotic degeneration with resulting general peritonitis. Forget, if you will, all other surgical pathology, but remember those two facts; upon them is based proper treatment and the justice of claiming appendicitis as a purely surgical affection, and whoever doubts their truth, him I invite to be present at my operations until conviction is forced upon him.

I shall not detail the more minute changes; our patients require pathologists for the living rather than pathologists for the dead—if I may use these terms; they need diagnosticians of disease by the bedside infinitely more than recognizers of morbid tissue at the laboratory.

It is the diagnosis, then, which is of supreme importance; and this ordinarily is not difficult. But first let me utter one word of caution: No frequent disease presents its signs and symptoms in such varied form and locality as appendicitis; make it a rule, therefore, in *all* abdominal cases to first exclude appendical irritation, because careful examination will often reveal as due to it affections otherwise apt to be classed as "entero-colitis," "acute dyspepsia," "cholera morbus," "biliousness," etc.

In all inflammations of the appendix, not entirely chronic, there are three "cardinal symptoms," viz., pain, tenderness, and rigidity; and of these pain is, in every variety, by all odds the most significant, so much so that I regard with suspicion every clinical history with a "bellyache," inflammation of the bowel, neuralgia of the stomach, and affections given in similar terms. But the pain of appendicitis has certain characteristics: above all it is paroxysmal, cramp-like and colicky, and may at intervals almost disappear. As to its locality, it is usually first referred to the umbilical and epigastric regions, becoming localized in the right iliac fossa only after the lapse of several hours, and that not in all cases. It is upon this point that egregious errors have been committed, so many of which I have seen that I should like to have emblazoned upon every house-top this sentence: The pain of appendicitis is neither always nor necessarily referred to McBurney's point; and pain elsewhere by no means excludes appendical inflammation. And if you ask me the reason, I have merely to call your attention to the variability in position of the appendix, the different parts of it affected, and the diverse involvement of the sympathetic nerve plexuses, to make my remark appreciated. For instance, pain and tenderness on the left side are commonly noted, and indicate that the appendix points south—rarely east—and occupies the pelvis; in such cases vesical symptoms are common and occasionally the pain is referred along the course of the spermatic cord, and may even cause retraction of the testicle, as in kidney-stone.

If the appendix is behind the cecum and points north pain may be referred to the back, to the kidney or to the liver, and it is then that skilful examination is needed to elicit, by palpation, the tenderness complained of subjectively. Too often have I seen in consultation, practitioners, after a few ill-directed punches, assert the absence of abdominal tenderness, when careful, deep palpation revealed a small, but exquisitely painful spot in the loin, pathognomonic of appendical disease. In fact, many a doctor, despite sufficient experience, never learns the art of palpation, since lightness of touch and knowledge of what to find are wanting, and thus many appendicitis cases are *overlooked*.

Examine first away from the seat of disease, and slowly and gently approach the tender area. A localized spot of extreme tenderness is probably the surest *indication of pus formation*; conversely, abrupt cessation of such pain is apt to denote complete gangrenous change and paralysis of the peripheral nerve filamen by toxin absorption. In addition to tenderness, palpation determines the presence and degree of rigidity. This is usually well marked and most intense over the inflamed appendix, but sometimes the rigidity of the entire abdominal wall is such as to preclude the possibility of local examination. Other symptoms of appendicitis—vomiting, diarrhea, constipation, etc.— I shall not consider, except to say that in appendicitis the temperature record is utterly untrustworthy and gives no reliable data in regard to pus, which, if encapsulated, may develop quite as well with a normal temperature as with an elevated one. Nor do I depend to any extent on blood examinations; a leucocytosis of over 20,000 usually indicates pus, unless either shut off by adhesions or the individual is overwhelmed by septic absorption. In fact, in appendicitis I have never learned by laboratory methods what was not as surely obtainable at the bedside.

I shall merely refer to the differential diagnosis of appendicitis. In men it is concerned especially with affections of the kidney and gall-bladder—calculi for the most part—while in women uterine and ovarian disorders are added. Occasionally the diagnosis is difficult, but in the vast majority of cases an accurate history, careful palpation and a due regard for the three cardinal symptoms—pain, tenderness and rigidity—readily suffice to distinguish appendicitis from other diseases.

It may be well to allude to the similarity between typhoid and appendicitis when both are in the early stages, and despite the Widal test such cases require much consideration. The slow onset, headache, temperature record, and epistaxis point to typhoid; while in appendicitis the local manifestations are usually more marked. As I have said the symptoms of appendicitis are seldom in proportion to the appendix lesions; let it suffice therefore to diagnose early the inflammatory involvement, which is of itself proper enough indication for rational treatment; and if you ask me what this is to be, I answer: There is but one treatment for appendicitis, viz., the aseptic scalpel of the surgeon, and it should be called upon as promptly as the diagnosis is made.

I know that some will recall cases apparently cured without surgical interference, and I recall them too, for in my experience they were on the operating-table with gangrenous appendicitis and abdomens full of pus, the saddest sights in surgical practice; for the first attack of inflammation creates a locus minoris resistentiæ for the later development of bacterial destruction. Clinical experience, unbiased judgment, therapeutics itself teach the absolute inefficiency of drugs to control or even affect a progressively inflaming appendix, and in the face of these facts medical powerlessness becomes by delay medical dawdling; and when, in appendix cases, I encounter pus, developed in an acute exacerbation after an interval of supposed safety, I realize that some one has blundered—either the physician, in not insisting on operation, or the patient in refusing it. In such instances allowing pus to be present is almost a crime, so easily averted is it by an early operation in itself practically without mortality. In fact I regard the medical treatment of appendicitis as high-grade "Christian Science."

As for the intervals after an acute attack, I consider them as absolute indications for operation. How often has a flourishing life been blighted by blind confidence in their permanence; how often are they but the inception of that quiescent repose that ends in the eternal rest of the grave!

The very history of appendicitis shows the necessity and growing appreciation of early surgical interference, and it is this practice which I both have and shall continue to reinforce with all my strength. It is the duty of our profession not to be scientific merely, not to be experimental alone, but to be life-saving, and this is the especial province of early operation in appendicitis.

DISCUSSION.

Dr. DeLancey Rochester, of Buffalo—I want to say a word from the standpoint of the physician. I agree entirely with all that Dr. Deaver has said, so far as I heard. I regret that I did not hear his remarks concerning the morbid anatomy and symptomatology of the disease. I only wish to add one or two words upon the subject of diagnosis and treatment. I want to make a strong plea for the value of the blood count in the diagnosis of these conditions during the acute inflammatory state and, particularly, during pus development. I have in mind several cases in which the blood count was of great value in determining purulent inflammations. I was called in to see one case during the absence of the attending physician. I was informed that the case was not one for operation, that an operation was not indicated on account of the weak condition of the patient. There was abdominal tenderness which was diffused generally through the pelvis, more particularly in the region of the appendix, and very markedly tender at McBurney's point; there was no tenderness above that point. This tenderness had existed for some time. The family was decidedly opposed to operative interference. Finally, a blood count was made and we found 56,000 leucocytes in a cubic millimeter; I then told them that an operation should be performed. In order to be certain several counts were made in succession, and the number of leucocytes never went below 15,000. An interesting point in reference to the blood count was that the leucocytosis varied with the temperature; with an elevation of temperature there was an increase in the leucocytes and *vice versa*. An operation was performed and an appendicitis was found to be present but complicated with disease of the ovaries. I think that, in this case, the blood count was of value in that it made me insist upon an operation. Dr. Deaver has stated that we may mistake disease of the gall-bladder for disease of the appendix; that they may be mistaken for each other. I wish to relate a case, occurring in the practice of Dr. Stockton, which I saw with him on several occasions. A young woman entered the hospital who had great pain and tenderness over the whole of the right side of the abdomen. The diagnosis made was that she was suffering from gall-stones. A blood count was made, a leucocytosis was found to be present, and it was thought that she had a purulent inflammation of the gall-bladder. An operation was performed, the gall-bladder was opened and pus and gall-stones were found. The patient improved for twelve hours and died within twenty-four hours. At the autopsy it was found that gall-stones had perforated the appendix, and that the patient had died from appendicitis in connection with the gall-bladder trouble.

As regards the treatment I believe that the aseptic scalpel is the only one for appendicitis in cases where it can be used.

Dr. J. V. Kelly, of Philadelphia—I think that, after the first twenty-four hours, a medical man should not attempt to treat a case of this disease. I have never regretted sending for Dr. Deaver, but have regretted not having sent for him early enough.

Dr. Frank D. Smythe, Memphis, Tenn.—I am prepared to agree with Dr. Deaver in toto. My experience in the management of appendicitis bears out the truth of every point he has made. Appendicitis is essentially a surgical disease; and a physician essaying to treat a case of appendicitis without the aid of a surgical colleague should possess considerable diagnostic skill in order that the proper time for operation could be determined. If the diagnosis were made early and the patient subjected to immediate operation you would lose none of your cases of appendicitis. The operation should be performed before the appendix becomes the site of an abscess and before the peritoneum shall have been invaded. At this time the operation can be performed quickly and safely and without risk of contamination of the peritoneum. The operation is a perfectly safe one in the hands of a skilful surgeon—practically without risk if performed promptly after its early recognition.

I have never lost a case of appendicitis when operated upon during the first day of attack. In this disease all cases should be subjected to immediate operation if recognized at the onset and seen by a competent surgeon. During the past year I have operated upon ten cases of septic lymphangitis and peritonitis following gangrenous appendicitis after perforation with 100 per cent. mortality. In none of these cases did I entertain any hope of recovery. I do not believe that a case of general septic peritonitis can be saved with or without an operation; I have never seen a case of this character reported as cured, and certainly have seen nothing of the kind in my practice.

No man can say how a given case of appendicitis will terminate, regardless of the mildness of the symptoms, if treated medically. It is impossible to predict what twenty-four hours will bring forth.

The mortality of appendicitis depends upon where the appendix points in the event of rupture, and not in the least upon the plan of campaign pursued if managed medically. Dr. Deaver has just said that the medical treatment of appendicitis is nothing more nor less than high-grade "christian science," and that the only legitimate way of treating appendicitis is with the aseptic scalpel in the hands of a conscientious and skilful surgeon. I agree with the essayist in every particular.

Dr. J. A. Witherspoon, of Nashville, Tenn.—I have listened with pleasure to the remarks made by Dr. Deaver and my confidence in him has never slackened since he was my teacher. I rise to-day to say that if the medical treatment of appendicitis is to be according to the belief of the "christian scientists," then the man who has a little pain in his belly, with a little temperature and with very few physical signs, who submits himself to operation, that man is as brave as Julius Caesar and has the faith of a Daniel. Now, gentlemen, we, as general practitioners, must realize that appendicitis is both a medical and a surgical disease. There are many cases that are mainly surgical. There are many cases of appendicitis that you and I have seen get well from the medical treatment, by placing the patient in bed, at once stopping all nourishment, applying ice-bags over the appendicular region, keeping the patient perfectly quiet, and using rectal enemas; with such treatment I can see no reason why many attacks of appendicitis will not end in recovery. Take the experience of my friend from Memphis who has just addressed you; he has lost 10 cases from operation. How many have lost 10 cases without operation? I believe that the proper course to pursue in these cases is to let the physician and surgeon go hand in hand; let the surgeon be urged to meet the emergency of perforation or of the abscess. These cases should be carried through the acute attack and, if an operation is demanded, let it be done during the interval. Eighty per cent. of the cases of appendicitis get well without the knife. But, if we can have such a skilled man as Dr. Deaver with us, he may save every case if seen in the primary stage, but we are not all of us fortunate enough to be able to call in Dr. Deaver, or as skilful a man, and every scalpel is not aseptic. We all know that in the smaller places if such extreme views prevail and men often incompetent undertake this operation that many lives will be sacrificed on the altar of fanatical surgery.

Dr. Boardman Reed, of Philadelphia—I agree with Dr. Deaver in the main, but I can not agree that at all times and in all places the aseptic knife is the only remedy in appendicitis. I agree, however, that in large cities, in hospitals with their skilled abdominal surgeons, with trained nurses, and all the paraphernalia and conveniences for clean and good work, that an operation performed on the first day, and perhaps on the second day, would be the most conservative; but, if in the country far from any hospital, from skilled surgeons and trained nurses, etc., I believe that we must then think of other remedies besides the knife. If one can not get a trained surgeon and if the case has gone on to the third day I think it is sometimes safer to treat the case conservatively by rest, poultices and starvation and help perhaps from laxatives, calomel, or opium, than to resort to surgery.

I wish to say a word in regard to the chronic cases of appendicitis. Here the main thing is to prevent. It is a well-known fact that most of these cases do not arise from concretions, or seeds, as was once thought, but from an extension of a catarrhal process involving the colon, chronic, insidious and often unrecognized. I think the symptoms that precede chronic appendicitis are not frequently enough recognized. They nearly always include, vaguely, impaired health, constipation or diarrhea, anemia, a lowering of the strength, general malaise, etc., symptoms which give a warning that something is wrong. The patient then does not need so much a surgeon as he does a skilled clinician, one skilled in palpation, skilled in recognizing the early signs which tend to cause catarrh of the appendix. Besides recognizing the catarrhal condition in the bowels, besides palpation and recognizing the tender spots over the involved portions of the intestine, a more rigid condition of the muscles on the right side of the abdomen can usually be made out and there are also signs to be discovered in the urine which will aid us in making a diagnosis if in doubt, i. e., the presence generally of indican or the aromatic sulphates, or both, together with an increased total acidity of the urine.

Dr. I. N. Love, of New York City—We all know what the position of Dr. Deaver has been and that it is a definite one; we all know the position he has held for a long time. We also know the position held by Robert T. Morris, and other experts, from a surgical standpoint. If we who are specialists in internal medicine study the question carefully, we must study it from both the standpoint of medicine and surgery. We must study not the theory but the conditions confronting us. Every case is a law unto itself. In every suspected case of appendicitis it is highly important that a competent physician, a good diagnostician, be called in early. We all know that every case of cholera morbus, every case of catarrh of the bowels, every case of ptomain poisoning, or suspected typhoid fever, every case of abdominal disturbance in fact is a possible case of appendicitis in disguise. Speaking of symptoms, whenever I have been called to see a case giving evidences of the disease along these lines I have observed that rigidity of the right side of the abdomen is a fairly positive symptom. Nature is placing a splint upon the disturbed bowel by making rigid the abdominal wall. Tenderness at a given point goes without saying. If the irritation be discovered early enough we usually assist Nature by emptying the canal and placing the patient at once at rest, starving them, placing an ice-bag over the seat of the trouble and then have an ideal surgeon constantly in attendance, ready to meet any emergency that may arise. If no emergency arises then we should continue to treat the patient along the lines indicated, and an operation can be done at our pleasure. In my own judgment operation should be done through fear of recurrences, although a patient may escape such recurrences. If the conditions are ideal, and if Deaver, Morris, Price, or other well-known abdominal surgeons could be had, even if it was at the country crossroads, I think an operation may be done; but in an average case of appendicitis I would trust to quiet, diet, starvation, ice-bags, and time.

Dr. William Bailey, of Louisville, Ky.—From the standpoint of the general practitioner, I heartily approve of all contained in the paper read by Dr. Deaver. In doubtful cases I am always ready to have an exploratory incision made for the purpose of clearing up the diagnosis. I have no confidence at all in the medical treatment of this disease. I make this remark in the face of the fact that many cases do recover without operation; so far as I know, they did not recover through any virtue of the treatment employed. I can recall cases of appendicitis that were not operated upon, that have gone for more than forty years without recurrences of the attack; but I have seen so many that did not come on after any catarrhal condition but as a thunder-bolt in a clear sky and in twenty-four hours were in an inoperable condition. In cases of doubt as to diagnosis I am always ready for the surgeon to make an exploratory incision. I do not believe that such an incision is a factor at all in the cause of death in such cases. I doubt very much the reports made in the papers that the patients died from the surgical operation; they died from disease which surgery was not able to relieve. I do not believe that any case, no matter what the conditions are, can be operated upon too soon, and I doubt if it is ever too late for operation.

Dr. C. W. Lillie, of East St. Louis, Ill.—To illustrate how rapidly an apparently latent case of appendicitis may develop, I wish to relate one in which I have been particularly interested, occurring in my only son. This young man, 21 years of age, robust, hearty, a football player and a general athlete, appeared all right at noon, but one-half an hour later, during my absence, he was taken with severe pain in the abdomen, which at once showed the place of development of a hernial tumor; my attention was called to that when I returned one-half an hour later. I was not aware that the young man ever had a hernia. When my attention was first called to it signs of collapse threatened and I feared that the young man would die from some cause apparently unaccountable to me. I had him taken to the Jefferson hospital in an ambulance. While in the ambulance on the way to the hospital the tumor entirely subsided and the pain disappeared, so that on arrival at the hospital he walked up one flight of stairs to his room, and operation was deferred until the day following. Twenty-four hours after the first advent of pain he was operated upon by Dr. Waldo Briggs, who found that he had to deal with about 5 inches of the ascending colon which was gangrenous, and that 4 or 5 inches more of it was in such a congested condition that at least 8 inches must be resected; fully 5 inches of the ileum was also in a partially necrotic condition and the entire 13 inches of the intestine was removed. The appendix had sloughed off in nearly its entire length. Resection of the bowel was done, the ileum and the colon were joined by the Murphy button and the patient made a good recovery. The points of particular interest in this case were the suddenness with which the alarming symptoms came on and the complication of a hernia which alone was believed to be the real trouble. As a result of this I am of the opinion that we should never allow our cases to go too long without operation. Since the occurrence of this case I have had another which happened in a hearty young man; within a few hours after its development an operation was done and there was found a gangrenous condition which with a few hours more delay would have necessitated an almost similar operation.

Dr. H. S. McConnel, of New Brighton, Pa.—It seems to me that we are not recognizing the fact that there are two treatments of appendicitis, the medical and the surgical; when the general practitioner is called to see a case he considers it a medical case, but for him to treat every case of pain in the abdomen as one of appendicitis I think is a great mistake. I think it is his duty to treat every case of pain in the abdomen unless he is positive that he has a case of appendicitis to deal with. One should bear in mind that there is not always a rigidity of the rectus muscle nor pain in the right side, for often they are on the left side of the abdomen. There is no doubt in my mind but that a severe case of appendicitis should be operated upon so soon as diagnosed. I have seen men come here who preached that we should wait twenty-four hours before resorting to operative interference; but I think that if the patients were treated, as they should be, with ice, saline solutions, etc., we will not make many mistakes.

Dr. Frank Warner, of Columbus, Ohio—I believe that there is but one time to operate in cases of appendicitis, and that is when the diagnosis is made, and the best way to make that diagnosis is by the presence of pain, tenderness and rigidity over the region of the appendix. Whenever these symptoms have arisen I must take issue with Dr. Love when he makes the statement that "then an operation can be done at our pleasure." Again, I do not approve of the method referred to by the gentlemen who preceded me, that we should wait awhile. After the diagnosis is made I think we would make an egregious error if we did not proceed at once to operation for the reason that we do not know what one of these cases will develop a gangrenous appendix. After diagnosing a case, if you wait even over night either your operation is a useless one or else you have added greatly to the danger. It has been stated that we can not all secure the services of the greatest surgeons to operate for us; I think that any man, with a moderate degree of ability, is capable of doing this operation and with less danger to his patient than if he either waited for the presence of a great surgeon who is long in reaching the patient, or resorted to medical treatment. With pain, tenderness and rigidity present, and the diagnosis settled, we should decide at once to operate, and I do not believe in wasting time because every day added to the postponement of the operation adds to its death-rate.

Dr. A. F. House, of Cleveland, Ohio—If there is any general practitioner in the room who will point out to me how to discriminate between the so-called medical cases and those that are surgical, I will be greatly obliged to him. In my experience with these so-called medical cases of mild degree, after a certain time, may come an explosion, as it were, and the case becomes a fulminant one, and the patient died; I have never yet seen a case that terminated fatally from too early an operation, while I have seen many cases that have died because they were operated on too late. I am glad to be able to support the opinions expressed by the essayist.

Dr. Wm. M. Findley, Altoona, Pa.—I rise simply in the interest of the 20 per cent. You that were present at Atlantic City last year heard an able discussion on appendicitis and you remember that Dr. Senn made the statement that 80 per cent. of the cases recovered without operation. I rise in the interest of the 20 per cent. Personally, I would not like to be one of that 20 per cent. I do not believe that the medical profession need have 20 per cent. of deaths from this disease. The records of gentlemen who are not connected with hospitals and who operate in the homes and hovels in the country give a better record than 20 per cent. of deaths when the operation is performed early, at the time the diagnosis was made. I have recently heard it stated here that operations are performed upon cases of appendicitis thirty-six hours after the diagnosis is made, and this, too, in the cities. I certainly believe that, in the cities where there are hundreds of surgeons, that these cases should be operated upon at once. In the little town where I live the death-rate during this past year was about one per cent. where the cases were operated upon within twenty-four hours; but, after thirty-six hours, I do not think such a good result can be obtained. I sincerely hope that the medical men of the United States will get away from that 20 per cent. death-rate in appendicitis.

Dr. George F. Jenkins, of Keokuk, Iowa—There are cases of appendicitis that should not be operated upon, and I think it is absolutely wrong to operate upon every case so soon as the diagnosis is made. If the treatment is carried out in certain lines—rest, salines, ice-bags, etc.—and if the treatment is commenced early enough you will not be compelled to resort to operation in all cases. Operation is always indicated when suppuration occurs. Dr. Deaver says that no physician can foretell the danger in any case, and hence he would not take the responsibility of treating even a mild case unless permitted to operate immediately. Does he say to the patient: There is no danger in operating, I will certainly cure you? No; he is still unwilling to take the responsibility, but says: If you will take the risk, I will do the cutting. Every case should be treated either medically or surgically, according to indications present. Responsibility rests equally upon the physician, whether he chooses to operate or not to operate.

I claim that we should always treat the man who has pneumonia, not simply treat the pneumonia, and I insist that, for the same reason, we should always treat the individual case of appendicitis, and not simply treat appendicitis. Routinism is as reprehensible in surgery as it is in medicine, and hence I am opposed to cutting in every case of appendicitis.

DR. J. M. SPELMAN, of Anaconda, Montana—I desire to say a few words because I find that the gentlemen who live in the Ohio and Mississippi valleys find it difficult to secure a skilful surgeon. In Montana it is impossible to get Dr. Deaver, or any other noted surgeon out there; it is impossible to do anything but take right hold of these cases yourself and, I promise you, we do it. We find no difficulty in performing operations for appendicitis, but we do find difficulty in treating them on medical lines. It seems to me that the discussion that arises year after year in the American Medical Association does us more harm than good, because it often has been the cause of delay in cases that required immediate operation; the idea has become prevalent among the people that operation should not be performed at once and so they will not allow it sufficiently early. I feel that this operation is as much an emergency operation as tracheotomy or herniotomy as we were formerly impressed and that every good practitioner should know its technique.

DR. W. H. CHRISTIE, of Omaha, Neb.—As a general practitioner, I wish to speak briefly. Gambling, whether done as a private individual or as a professional man, is a bad business so far as the pocket-book is concerned in the former and one's standing in the community in the latter. These patients that died from the operation when it was performed in the latter stages might have lived if they had been operated upon at an opportune moment. Waiting before operating is gambling with human life. We can not tell, nobody can tell, what is going to happen when the appendix becomes diseased. Therefore, I do not believe in gambling with human life; we should urge operation immediately, as soon as the diagnosis has been made.

DR. JOHN B. DEAVER, of Philadelphia (closing the discussion)—So far as the value of the blood count is concerned I do not question it, not for one moment; but, where there are no facilities for such work, and where time is necessary in order to profit by such an examination, causing delay, then I am opposed to it; the patient's welfare will not admit such a delay.

I can not agree with all that has been said relative to the medical treatment of appendicitis. In cases that have recovered from an attack I believe that it is wiser to operate between attacks than to wait till another attack is ushered in; operate in the interval. I do not believe that there is a man living who can tell whether A., B. or C. can recover.

I maintain that it is all right for a surgeon, if properly trained and an anatomist, with experience and common sense, and with the facilities for operating, to operate so soon as the diagnosis of appendicitis has been made. I also maintain that the surgeon is better able to read the conditions inside the belly than a medical man.

I wish to congratulate Dr. Bailey; with his silver locks, he can teach all of you; I admire a man at his time of life who is abreast of the times, and I pray that we may have him with us for many years to promulgate views such as he has to-day, which must accomplish much good.

PRELIMINARY WORK.*

EUGENE S. TALBOT, M.D., D.D.S.

CHICAGO.

Many years ago it occurred to me that physicians could follow generally with advantage both in pathology and physiology the example of neurology and study the human body from the standpoint of both its embryonic and post-uterine evolution and from the standpoint of its degeneracy as well. It was long recognized that health simply constituted a balance and that disease meant the destruction of this balance with resulting undue predominance of some healthy function and the undue depression of others. Practically the same rule is followed by the chemist who controls his analytic experiments by his synthetic, and vice versa. Physicians and dentists generally in studying man as an entity, view the differences between the normal and the abnormal as of kind and not of degree. To avoid this error, I have studied the degenerate phases of man from the standpoints of etiology, physiology, and lastly and most important from the standpoint of embryology and post-uterine development periods. The result of these studies has been the general discussion of degeneracy as a phase of evolution, in "Degeneracy: Its Signs, Causes and Results," published in London in 1898. The local degeneracies either as an expression of general advance or its reverse have been outlined in my works upon "The Etiology of Osseous Deformities of the Head, Face, Jaws and Teeth;" "Irregularities of the Teeth and Interstitial Gingivitis or so-called Pyorrhea Alveolaris;" "Degeneracy of the Alveolar Process." It is now my intention to discuss one of the most important of local degeneracies so far as dentistry is concerned: Degeneracy of the Pulp. Last winter I arranged with Chicago dental surgeons that extracted teeth should be saved for me. My assistant collected from their offices every afternoon at 4 p.m. The teeth were then cracked open at my office, the pulps removed and placed in Müller's fluid and 1 per cent. formalin before 6 p.m. From 1958 teeth obtained, 1017 pulps were removed. Macroscopically the pulps were thus divisible: Normal, exposed, inflamed and suppurating, mummified, calcified and calculous; fungoid, with exostosed roots; loose teeth abrasion; pulps destroyed with arsenic and deciduous teeth pulps. Sound erupting third molars and bicuspids extracted in regulation had been placed in Müller's fluid ere they came under my observation.

In nearly every case the pulp could be lifted out of its chamber so far as the apex of the root. In every case, the root had to be crushed before the pulp could be detached. Pieces of the cementum almost invariably adhered to the pulp, which required considerable force to detach. The slight adherence of pulps to the chamber was due to anatomic construction. This peculiar relation of the pulp to the walls of the canal becomes obvious when attempts are made to remove it in single-rooted teeth, after application of arsenic. The nerve broach not infrequently carries the pulp with it in passage toward the apex. The pulp often comes out in doubled-up contracted mass. Sometimes it comes away in pieces. and sometimes the pulp is not entirely detachable from the end of the root. The claim that pulps immediately removed from the teeth after extraction adhere to the wall of the canal is not borne out by experience. If nerve fibers radiated from the pulp and extended into the dentine it would be impossible to remove the pulp from its chamber. The pulp, however, can not be removed from the end of the root without breaking; it therefore seems evident from a macroscopic standpoint that nerve fibers as such do not enter the dentine. In removing the pulp it always remained *in toto* on account of the strong connective tissue.

A point of great interest in connection with pulp adhesion to the root is that not only the degeneracy of the pulp, but also of the tooth likewise. In development of the tooth, calcification begins at the crown and extends toward the apex. Calcification takes place at the periphery of the root and extends toward the center. A marked opening results with a large primitive organ (the pulp) until the apex is reached, when it closes. This closing often continues after the crown has erupted. The foramen is almost completely closed. What was

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

to buy every book published in his own branch, since so many are merely reiterated statements, by worthy investigators, not brought up to date or not original. Owing to the scarcity of accessible works even in the majority of our large central cities, the task of "looking up literature" is by no means easy or worthily done, oftentimes many essays and papers scattered through the numerous journals being out of reach. Better libraries are needed.

Perhaps the earliest mention of the dental pulp is by Galen,[1] who states: "He felt the pulsation in a tooth that was aching in the same way as any other inflamed part. I know that the seat of one pain was in the tooth and the other in the gum." "To Galen we may also ascribe the discovery of soft nerves supplied to the teeth."

In 1771 John Hunter noted the building up and closing in of the pulp cavity when attrition has worn the teeth, as did George Prochaska (1780) in his work published in 1800. Besides these, we may note Thomas Bell, Bertin Rousseau, Lent, Raschkow, Richard Owen, Alexander Nasmyth, Kölliker, R. T. Hulme, E. Albrecht, R. Hohl, J. Bruck Junr, F. Ulrich and many others, whose papers chiefly relate to calcifications in the pulp and pathology.

About the earliest histologic point I have found so far seems to be by Paul B. Goddard,[2] who described the pulp as composed of granular matter invested by a delicate membrane or epithelium.

Prof. L. S. Beale, in 1865, states the pulp tissue is not converted into dentine, neither does the dentine, nor tissue from "which it is formed, exhibit any characters justifying in stating it to be connective in origin. Dentine is only produced by the agency of the so-called cells." The mass of the pulp is composed of a single form of connective tissue with numerous oval and triangular corpuscles (germinal matter) not unlike the mucous tissue of the umbilical cord. This will seem to be foreign to the title of this paper, but I find in almost all articles the close relation of dentine and its histology and origin the chief topic.

Kölliker[3] summarized the dental tissues in one of the first text-books, which held its place for many years. The odontoblasts were formally termed "dentinal cells" (Elfenbeinzellen). Kölliker termed this entire layer of cells *membrana eboris,* because after the pulp has been withdrawn it usually cleaves to the inner surface of the tooth in the form of a continuous membrane-like layer. Kölliker, Klein and others, state that odontoblasts excrete dentine, differing from Waldeyer, who has a most complete and satisfactory theory as regards the development of the teeth. He also makes mention of Sharpey's fibers being formed in the cementum, and agrees with Boll that the odontoblasts (a term originating with Waldeyer) send fibers and connect with each other by lateral processes. He also edits the article on "Formation of Dentine,"[4] which formed the basis of a controversy with Prof. H. Hertz in *Virchow's Archiv,* and was used by Franz Boll in order to explain the contradictions of the two investigators and so form an independent opinion.

Franz Boll is an investigator to whom we owe much. His work[5] is standard to-day, even in the light of so much new research by better methods and apparatus. Professor Waldeyer, of the University of Breslau, eminent as a histologist and microscopist, says in his famous essay on the mouth and development of the teeth: "We owe to Mr. Boll (a medical student at Bonn, when his essay was written) the first definite knowledge of the condition of the nerve fibers in the teeth." Boll says we *never* secure the whole pulp or *all* the soft part of it, as the odontoblastic processes project into the tubes of the dentine. Let one be ever so careful in extracting the pulp from freshly cracked teeth, a trace of this peculiar layer will rarely be found on the surface of the pulp. But if cracked and then hardened in chromic-acid solution for an hour, using considerable care in removing broken dentine and a sharp knife, one may sometimes obtain the superficial layer of the pulp *in continuo.* The processes which are enclosed in the dentinal tubes generally break close to the body of the cell, but by a skilful movement of the knife they may sometimes be successfully extracted of considerable length from the tubules.

J. Tomes described nerve fibrils in the dentine continuous with the pulp-network, and considered these fibrils to be the cause of sensitive dentine. Boll, in his demonstrations, used the long incisors of rodents, as guinea-pigs, rabbits, etc., which may make some difference as regards the attachment of the pulp to the dentine.

Goodsir's[6] work was received without question by most anatomists, if not by all, inasmuch as it gave a very definite intelligible description of observations in place of vague general notions, especially as regards the development of enamel, which was, in 1863, clearly demonstrated by Professor Kölliker.

Legros and Magitot in their work[7] give a very excellent résumé of much value. This work, published in 1873, was translated in 1880 by M. S. Dean of Chicago.

J. Raschkow[8] mentioned that the teeth developed under the mucous membrane and enamel organ. He described the blood supply of the pulp, by two or three arteries and asserted that the pulp has one large and a few smaller nerves, the latter breaking up near the surface into an exceedingly fine plexus, called the plexus of Raschkow. Boll and others suggest that fine filaments are given off from this plexus which inosculate with the branches of the odontoblast cells, but as yet this connection has not been demonstrated and accepted as a fact.

Neumann,[9] in 1863, demonstrated the dentinal sheaths. Boll following out the dental nerves in their further course, more recently. Tomes[10] has most carefully and successfully continued the study of the finer points of dental structure and, by first demonstrating the dentinal fibers, opened the way to a correct interpretation of the nature of dentine.

Lent[11] demonstrated the dentinal processes of odontoblasts. Klein[12] says the cells beneath the odontoblasts are spherical and nucleated, and, according to his view the dentinal process is derived from these cells and it from odontoblasts.

Retzius[13] observes by the use of Golgi's stain, that the nerve fibrils of the pulp appear to penetrate between the odontoblasts and terminate between them and the dentine. Rose[14] says, with increasing age the odontoblasts appear to suffer from atrophic changes.

Erwin Hoehl[15] states that three kinds of cells occur in the pulp at different life periods: 1, the outermost peripheral layer of branched cells; 2, centralward the conjugation cell layer, containing the elementary or primary odontoblasts, the largest process of the cell becoming the future dentinal fibril; 3, secondary odontoblasts (dentinoblasts) by conjunction of the first and second layers.

R. R. Andrews[16] states that odontoblasts in forming once a large pulp containing nerves and blood vessels tapers down to the minutest size with but only one or two blood vessels and nerves remaining. In the lower mammals teeth have open ends with large pulps. These furnish sufficient nourishment to the teeth and resistance to decay. Of the 1017 pulps collected 131, or 11.9 per cent., were more or less mummified. While no special attempt was made to determine the extent of mummifaction, 75 per cent. of the 131 seemed mummified. The remainder had varying degrees of mummifaction beginning at the apical end. The extent of bloodletting at the time of extraction governed the degree of mummifaction. The question further arises, What amount of blood did the pulp contain at the time of extraction? Did the closure of the apical end of the root cut off the blood supply? It is certain that teeth with mummified pulps were hard, dense and comparatively difficult to crack. In pulps partially mummified there was a demarcation between the part filled with blood and the dried end. In the dried end, mummifaction was complete. The dried specimen was removed from the end of the root with as much difficulty as the normal pulp, while the main part could be readily lifted out of the chamber as there was no adhesion. The pulp can become completely mummified in six to twelve hours. All the teeth from the same mouth were sometimes mummified. The pulps in abraded teeth had receded and been almost obliterated. Recession is sometimes followed by obliteration of the pulp chamber. In most cases, the filling of the pulp chamber does not follow. Blood supply is almost if not quite exhausted. In cases where the roots were exostosed the pulps were often almost obliterated with corresponding filling in of the pulp chamber. In other cases mummifaction of the pulp occurred. There were seventeen (1.5 per cent.) calcified and calcalous pulps. In some the tooth had to be completely crushed to remove the calcified mass which had adapted itself to the walls of the cavity. In others the pulp could be removed in its entirety, so complete was the calcification inside the pulp inself. There were four fungoid pulps of 1017 pulps. In all four, pulp stones could be felt. The percentage of minute pulp stones can be determined by the microscope alone.

In interstitial gingivitis, where the alveolar process has receded and the roots of the teeth have been exposed for some time, the pulp recedes and the canals become filled with dentine. Although the pulps are alive, the substance in the tubuli decomposes and the odor is more penetrating than that from dead pulps. The dentine becomes dark and twice as much force is required to break open the tooth than in the normal variety. These teeth are brittle and fly to pieces, while the normal tooth splits lengthwise.

The tooth is the lowest structure in the body since it is formed of material which can be destroyed by disintegration only. The pulp is a temporary organ, having attained its normal size and hence been at its best when it commences to form the dentine. The apical foramen is largest in the lower vertebrates. Pulp stones or secondary dentine are the commencement of degeneracy. No lymphatics (Sudduth) exist in the pulp, since it is a formative as well as a degenerative organ. One hundred and thirteen, or 11.1 per cent. of the pulps examined, were exposed, infected with pus infection and sloughing. The inflammation sometimes extends throughout the entire pulp. Sometimes one part or side only is affected. In the case of a molar, inflammation often extends upon the side of the pulp and into one root. The other side of the pulp root or roots remains normal or is but slightly affected.

These teeth and pulps were turned over to Drs. Latham and Anderson for cutting, staining and mounting for the microscope.

THE LITERATURE OF THE PULP.*

VIDA A. LATHAM, M.D., D.D.S., F.R.M.S.

CHICAGO.

In reviewing the work done on the dental pulp, it appeals very strongly to the operative side. In other words, the majority of the papers concern themselves with the pathologic conditions, which include special and general pathologic states from inflammatory to degenerative, and bacteriologic gangrene to formation of pulp-stones and the treatment of the same. One noteworthy point is the constant effort directed to the "killing of the pulp" by every known means and the very little encouragement to try to save the "formative organ." In these days of advancement of the histophysiologic research and the introduction of new methods and chemicals, it seems strange the dental-pulp appears to have been considered as either completely worked out or not so important an organ as enamel or dentine or even the peridental membrane. Yet its development, structure, functions and variations are hardly understood—and we expect to cure its ailments. It is true a great deal has been investigated and many essays and papers presented from all parts of the world, but very little truly scientific work has been completed. Take the latest works on dentistry and see in what small space the dental pulp is mentioned and the debatable points occurring in almost every line. Even the dentine seems to be of greater importance, and yet the question may be asked: "Should we have a dentinal layer if the pulp were not formed early and were not of primary importance as a formative papilla for its development?"

In this paper, so far as possible, references to the operative treatment of the pulp have been excluded, and in considering the anatomy, histology and especially the development of the pulp, many authors have described the neighboring structures of odontoblasts, dentine and enamel, it being impossible to separate them wholly from the pulp. Anyone wishing to study the latter must be willing to examine also the former.

Dentists are now waking up to the fact that we must have more preliminary training in the elementary branches, and schools of dentistry are constantly improving. It would be a worthy object to found grants, scholarships and opportunities for original research work to post-graduates or advanced workers, instead of such memorials as oil-paintings, busts, etc. The former would carry far more weight, would perpetuate memory in a nobler way, and reach to almost every clime and class by constant quotation, thus enriching science and benefiting thousands of suffering humanity. How many libraries contain works on dentistry accessible to the student that are of recent date or valuable in looking up the subject? It has been said that publishers object to giving the large medical and scientific libraries a copy of a book for fear of lessening its sale. Personally, I think this objection should not be sustained, as many people who note a new book in a library or store, finding it suited to their needs will buy a copy to have at hand. Hardly any one man (even if he could afford it) cares to buy every book published in his own branch, since so many are merely reiterated statements, by worthy investigators, not brought up to date or not original. Owing to the scarcity of accessible works even in the majority of our large central cities, the task of "looking up literature" is by no means easy or worthily done, oftentimes many essays and papers scattered through the numerous journals being out of reach. Better libraries are needed.

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

Perhaps the earliest mention of the dental pulp is by Galen,[1] who states: "He felt the pulsation in a tooth that was aching in the same way as any other inflamed part. I know that the seat of one pain was in the tooth and the other in the gum." "To Galen we may also ascribe the discovery of soft nerves supplied to the teeth."

In 1771 John Hunter noted the building up and closing in of the pulp cavity when attrition has worn the teeth, as did George Prochaska (1780) in his work published in 1800. Besides these, we may note Thomas Bell, Bertin Rousseau, Lent, Raschkow, Richard Owen, Alexander Nasmyth, Kölliker, R. T. Hulme, E. Albrecht, R. Hohl, J. Bruck Junr, F. Ulrich and many others, whose papers chiefly relate to calcifications in the pulp and pathology.

About the earliest histologic point I have found so far seems to be by Paul B. Goddard,[2] who described the pulp as composed of granular matter invested by a delicate membrane or epithelium.

Prof. L. S. Beale, in 1865, states the pulp tissue is not converted into dentine, neither does the dentine, nor tissue from "which it is formed, exhibit any characters justifying in stating it to be connective in origin. Dentine is only produced by the agency of the so-called cells." The mass of the pulp is composed of a single form of connective tissue with numerous oval and triangular corpuscles (germinal matter) not unlike the mucous tissue of the umbilical cord. This will seem to be foreign to the title of this paper, but I find in almost all articles the close relation of dentine and its histology and origin the chief topic.

Kölliker[3] summarized the dental tissues in one of the first text-books, which held its place for many years. The odontoblasts were formally termed "dentinal cells" (Elfenbeinzellen). Kölliker termed this entire layer of cells *membrana eboris,* because after the pulp has been withdrawn it usually cleaves to the inner surface of the tooth in the form of a continuous membrane-like layer. Kölliker, Klein and others, state that odontoblasts excrete dentine, differing from Waldeyer, who has a most complete and satisfactory theory as regards the development of the teeth. He also makes mention of Sharpey's fibers being formed in the cementum, and agrees with Boll that the odontoblasts (a term originating with Waldeyer) send fibers and connect with each other by lateral processes. He also edits the article on "Formation of Dentine,"[4] which formed the basis of a controversy with Prof. H. Hertz in *Virchow's Archiv,* and was used by Franz Boll in order to explain the contradictions of the two investigators and so form an independent opinion.

Franz Boll is an investigator to whom we owe much. His work[5] is standard to-day, even in the light of so much new research by better methods and apparatus. Professor Waldeyer, of the University of Breslau, eminent as a histologist and microscopist, says in his famous essay on the mouth and development of the teeth: "We owe to Mr. Boll (a medical student at Bonn, when his essay was written) the first definite knowledge of the condition of the nerve fibers in the teeth." Boll says we *never* secure the whole pulp or *all* the soft part of it, as the odontoblastic processes project into the tubes of the dentine. Let one be ever so careful in extracting the pulp from freshly cracked teeth, a trace of this peculiar layer will rarely be found on the surface of the pulp. But if cracked and then hardened in chromic-acid solution for an hour, using considerable care in removing broken dentine and a sharp knife, one may sometimes obtain the superficial layer of the pulp *in continuo.* The processes which are enclosed in the dentinal tubes generally break close to the body of the cell, but by a skilful movement of the knife they may sometimes be successfully extracted of considerable length from the tubules.

J. Tomes described nerve fibrils in the dentine continuous with the pulp-network, and considered these fibrils to be the cause of sensitive dentine. Boll, in his demonstrations, used the long incisors of rodents, as guinea-pigs, rabbits, etc., which may make some difference as regards the attachment of the pulp to the dentine.

Goodsir's[6] work was received without question by most anatomists, if not by all, inasmuch as it gave a very definite intelligible description of observations in place of vague general notions, especially as regards the development of enamel, which was, in 1863, clearly demonstrated by Professor Kölliker.

Legros and Magitot in their work[7] give a very excellent résumé of much value. This work, published in 1873, was translated in 1880 by M. S. Dean of Chicago.

J. Raschkow[8] mentioned that the teeth developed under the mucous membrane and enamel organ. He described the blood supply of the pulp, by two or three arteries and asserted that the pulp has one large and a few smaller nerves, the latter breaking up near the surface into an exceedingly fine plexus, called the plexus of Raschkow. Boll and others suggest that fine filaments are given off from this plexus which inosculate with the branches of the odontoblast cells, but as yet this connection has not been demonstrated and accepted as a fact.

Neumann,[9] in 1863, demonstrated the dentinal sheaths. Boll following out the dental nerves in their further course, more recently. Tomes[10] has most carefully and successfully continued the study of the finer points of dental structure and, by first demonstrating the dentinal fibers, opened the way to a correct interpretation of the nature of dentine.

Lent[11] demonstrated the dentinal processes of odontoblasts. Klein[12] says the cells beneath the odontoblasts are spherical and nucleated, and, according to his view the dentinal process is derived from these cells and it from odontoblasts.

Retzius[13] observes by the use of Golgi's stain, that the nerve fibrils of the pulp appear to penetrate between the odontoblasts and terminate between them and the dentine. Rose[14] says, with increasing age the odontoblasts appear to suffer from atrophic changes.

Erwin Hoehl[15] states that three kinds of cells occur in the pulp at different life periods: 1, the outermost peripheral layer of branched cells; 2, centralward the conjugation cell layer, containing the elementary or primary odontoblasts, the largest process of the cell becoming the future dentinal fibril; 3, secondary odontoblasts (dentinoblasts) by conjunction of the first and second layers.

R. R. Andrews[16] states that odontoblasts in forming the matrix of dentine give out minute globular bodies which form a layer of calcoglobulin, not being themselves any part of the matrix. The fibers within the tubes are formed from a separate cell, deeper in the pulp tissue, whose processes pass in through the protoplasmic mass of the odontoblasts to reach the dentinal tubes of the formed dentine.

BLOOD SUPPLY OF THE PULP.

Bödecker,[17] in discussing Mr. Witzel's work, says: "I have not been able to see an artery in a pulp as illustrated, though I will not say there may not be one." So far, he has only met with capillaries. Arteries go into the pulp and divide at once upon entering it. In fetal pulps, a number of arteries are seen extending to the base of the tooth, but on entering are only seen as capillaries.

Dr. W. H. Atkinson[18] says that no embryologists will state there are three coats on the vessels in the pulp; the large vessels are sinuses.

Dr. A. O. Hunt[19] notes Dr. Patrick's demonstration of the methods of blood supply to the follicle of the developing tooth. Specimens were prepared as follows: Injections of gelatin carmin were made through the carotid artery; sections cut from the jaw were put into absolute alcohol and ground down, no water being used, only alcohol to keep them wet. Examination of these specimens showed that the blood supply of the tooth did not pass directly from the artery through the foramen but was distributed through the cancellous bone by a number of small branches and all along the peridental membrane by a system of capillaries. He believed the nerves did not pass directly through the foramen but by a circuitous route accompanying the blood current. All the blood vessels stopped on the outside of the membrane and the supply was there taken up and distributed by a system of capillaries. A fetal (eight months) tooth showed this clearly and he thought it true of the developed specimen. He doubted the old theory that the artery and nerve fibers entered the foramen directly, and he also thought the office of the peridental membrane was simply to sustain what it has built up. In other words, the artery breaks into capillaries, passes into the cancellous bone about the teeth, is distributed to the peridental membrane, from it to the pulp through the apical foramen or a number of foramina in the root.

Black,[20] in discussing the above paper, agreed with Dr. Hunt in the statement that no direct branch from the dentinal artery enters the apical foramen and supplies the pulp as depicted in so many text-books; but that many arteries, branches from the main dentinal arteries, are distributed to the bone of the alveolus and the peridental membrane, forming a network which gives off branches that enter the dental foramen and supply the pulp. "In children you will find half a dozen, and before the root is fully formed you will find hundreds of them entering the pulp from all directions, but as the foramen decreases in size they are shut off until there is but one."

J. Leon Williams[21] describes the blood supply of the pulp as coming from two sources, namely, the pericementum and the medullary canal, and has observed in recently developed teeth small blood vessels passing from the pericementum through the side of the root into the pulp; also he notes an "intricate plexus of very fine blood vessels in the odontoblastic layer of cells."

H. H. Burchard[22] believes (though he has not demonstrated) that the pulp has an extensive collateral circulation, the branches of the inferior dental arteries anastomosing freely with the branches of the external maxillary, facial, coronary, mental, submental, sublingual, gingival, internal maxillary and its branches, other than the inferior dental. Cryer's dissections showed that in the lower jaw the inferior dental artery is the main supply.

In the embryo, as early as three months, a blood supply in the dentinal papilla is evident, vessels showing in the dentinal papilla (the future pulp) before the follicular walls (in part the future pericementum) is outlined. "When the dental tissues proper begin to form, the follicles lie in a gutter of bone, their bases (the future necks of the teeth) separated from the bone by a comparatively thin layer of fibro-vascular tissue in which lie the inferior dental vessels. At this stage, numerous arterial trunks are seen passing into the immature pulp." At seven months, the lateral blood supply (from the periosteum) is more marked than that from the base of the dentinal papilla and quite distinct from the vascular supply to the pulp. Bone forms around all the arterial trunks enclosing them, the vessels being at first enclosed by indifferent tissue, this becoming fibrous and finally ossification taking place.

Hertwig's "Embryology" describes the visceral arches at an early stage in the development of the ovum, and states that differentiation of the tissues of the visceral arches into bone, muscle fascia and glands, changes the anatomical relations of the arteries originally supplying the arches.

Burchard's conclusion is that the pericementum is supplied from arteries which enter the apical space in several branches from the dental arterial trunks and that there is free anastomosis with the vessels of the alveolar walls. The pulp is supplied by several trunks from the dental arteries. In case of obliteration of these trunks collateral circulation is established through the vessels of the pericementum and alveolar walls.

NERVE SUPPLY OF THE PULP.

Retzius investigated the endings of the pulp-nerves in fishes, reptiles, amphibians and mammals. He used the Golgi method and traced the nerve fibers to their terminal fibrillæ, which appeared under the dentine or on the free surface of the pulp, occasionally in the teeth of young mice, running between the odontoblasts and the dentine, but never into the dentinal tubules.

Huber[23] studied the nerve supply of the tooth pulp in dogs, cats, and rabbits, employing the *intra vitam* methylene-blue method of staining. He demonstrated that medullated nerve fibers going to the pulp in large bundles break up into small bundles which anastomose and form a plexus in the fibrous tissue membrane covering the under surface of the pulp. From this plexus smaller bundles of medullated nerves pass perpendicularly into the pulp and can be traced "to all levels of the pulp, some of them to the very tip." Besides these, many medullated fibers leave the bundles and approach the surface of the pulp near the lower surface of the odontoblastic layer, losing their sheaths or breaking up into branches, which are non-medullated with varicosities and nuclei and which branch and interlace with each other, forming a network under the odontoblasts. Terminal fibers given off from this network pass up between the odontoblasts and terminate in fine granules near the free ends of the odontoblasts. Somewhat rarely the fibers may be found crossing over the odontoblasts and ending between the odontoblasts and the dentine. In these findings, Huber coincides with Retzius and he states positively that he found no nerve fiber in the dentine and no fiber connected directly with the odontoblasts or with any other cell elements of the pulp. "The terminal fibrillæ or fine branches given off from them terminate in free endings between the odontoblasts or between these cells and the dentine and are not in connection with the dentinal fibrils directly or through the odontoblasts."

Morgenstern[24] endeavors to establish principally certain special points: 1, innervation of the blood vessels; 2, relation of the axis-cylinder to various cellular components; 3, the nerve endings; 4, structure of the nerve plexus beneath and within the odontoblastic zone.

1. The innervation is enormous. All the arteries, even the finest arterioles, exhibit an extremely fine and elaborate plexus. In the larger blood vessels, it shows a very regular arrangement of the fibers, one set running parallel with the blood vessels and another at right angles to them. In this way, each nucleus is made to rest, as it were, in a network of nerves. One or more axis cylinders are frequently found with the finest capillaries, not uncommonly embracing these spirals. This was especially easy to prove in the crown pulp of a calf. Morgenstern found similar formations in dentine that had been treated by the corrosive sublimate method (Golgi), and had afterward been colored with hematoxylin. The larger nerve fibers have Ranvier cells at fairly regular intervals; the finer ones have few cells or none at all, although they have many knobby enlargements, which appear in the finest fibers only as points.

2. Nerve endings in the pulp are difficult to determine as one can never assert with absolute assurance that where a nerve fiber appears to terminate, it does not really continue in some other direction out of your field of observations. I believe they terminate as free fibers, especially when they divide like a brush into a number of very fine threads. Many axis cylinders end in small knobby enlargements beyond which for the most part a very fine, short thread extends.

3. Between and below the odontoblasts the nerves frequently terminate in rounded cellular bodies, which could be better shown by another method, by means of which they are brought into sharper contrast with their surroundings. These bodies are identical with the terminal discs described above, we assume. Whether the nerves extend throughout the entire odontoblastic zone—a most important question—could be answered positively by Bethe's modification of the methylene-blue process. In the so-called horns of the pulp, more correctly the crest, the nerve fibrils are universally present between the elementary cells which are but imperfectly united to form odontoblasts. These nerve fibrils lie in close parallel lines and send out a large number of lateral branches, between the elementary cells which are side by side in rows. The fibers show by their marked blue tint and by the fact that they spring from the primary nerve fibers, that they are integral constituents of the nervous system which extends throughout the pulp. Dentine germs from human and animal fetal jaws treated by the anilin-blue methods of Ciaglinsky and others (Stroebe) showed the fibrils of Weil's zone to be colored blue, like axis cylinders, but that the dentinogenous substance was likewise colored blue. Where odontoblasts had been formed there was often seen narrow transverse strips of blue tint,[25] by which the odontoblasts seemed to be derived into segments.

Erwin Hoehl also saw this appearance but correctly explained them as fibrils of the intercellular network of nervous elements and this can be proved by the methylene-blue method, and Nikiforoff, also Morgenstern's formic acid was peculiarly efficacious. That cells which belong to the nervous system do occur between the odontoblasts is proved by preparations made with methods two (2) and six (6). The peculiar chemic and optic properties of the odontoblastic zone serve to explain why the morphologic constituents are so difficult to recognize both there and in the membrana præformativa. The nearer the odontoblastic zone approaches the dental process the more thoroughly does it seem to be filled with a hyaline substance which opposes an almost insurmountable obstacle to all investigations.

Whether ganglion cells occur in the pulp is perhaps answered by the methylene-blue test to the extent that remarkably large cells connected with at least two nerve fibers occur, especially near the larger blood vessels, that is, in the axial portion of the pulp.

SUMMARY.

1. The nerves of the pulp are divided into central and parietal nerves according to their location. The nerve branches of the parietal system are more slender, but much more numerous than those of the central. They are spread in two directions, axial and radial, the former following the long axis of the tooth, the latter that of the dentine canals.
2. Although belonging to the parietal system, its outermost stratum forms a system in itself.
3. More strongly developed nerve fibers of the central system form no proper plexus in the pulp; those of the parietal system form temporarily in the young pulps a plexus.
4. Medullary sheaths of the pulp are secondary formations only determined positively in teeth that have been cut.
5. Odontoblastic zone is transversed in the most varied directions by nerve fibers.
6. Nerve fibers terminate in several ways: *a*, free in the pulp; *b*, knobby enlargements with projecting supplementary fiber; *c*, disc bodies frequently seen in the odontoblastic zone.
7. In the central part of the pulp are some very large cells which may be considered as ganglion cells.
8. Different varieties of endings occur even in the enamel.

These remarkable results of Morgenstern's have been questioned by Röse, who thinks it a precipitate in the dentinal tubules and on the processes of the odontoblasts.

Dr. W. G. Aitchison Robertson[26] says "the odontoblasts in the teeth of oxen are bipolar, one process being a dentinal fiber and the other continuous with the nerves of the pulp. He thus regards the odontoblasts and dentinal fibers as becoming in course of development the terminal organs of the nerves of the tooth. These facts and the development of the dentine were made on the teeth of rabbits and kittens, in the former taking advantage of the aid given by feeding the animal for a time on food containing madder, which stains the dentine matrix produced while the madder is being taken just as it does the matrix of bone. The elongation of the dentine results from proliferation of connective tissue cells in a formative ring at the base of the tooth follicle. The thickening of the dentine results from new layers of matrix added from within under the influence of odontoblasts, not from interstitial growth which produces nothing more than a slight increase in matrix between the dentinal tubules in the crown of the tooth." To the question whether the nerve passes as a main fiber from the trunk nerve direct through the foramen, or are the nerves in the pulp continuous with the nerves in the pericementum, statements have been made that if the nerves extended through the foramina the broken nerve would be seen extending beyond the end of the root, which is never the case! If anyone will take the pains to examine the teeth as soon as extracted examples can often be seen with a projecting pulp or nerve (?) varying from one-sixteenth to one-eighth of an inch in length, some times even more. They appear as whitish threads coming from the apex, especially in cuspids, incisors and bicuspids, blanched on account of the sudden rupture and hemorrhage. Unless noted at the time, the shrinkage is so great it might not be perceived, though carefully fixed material will show the pulp in some cases, specimens of which I have now.

J. L. Williams emphasizes the vasomotor nerves of the pulp and pericementum, showing branches (nonmedullated) distributed to the blood vessels, he suggests that stimulation or injury of these nerves may paralyze the vasoconstrictor fibrils a short time before paralysis of the vasodilator fibrils occurs, thus explaining the engorgement of the vessels which strangulates the pulp in arsenical destruction of the latter. The origin of the vasomotor nerves, he states, is "in the upper jaw from the anterior palantine nerve, which, arising from the spheno-palantine ganglion, is connected with the sympathetic system through that branch of the Vidian nerve which arises from the carotid plexus; and in the inferior maxilla, their connection with the sympathetic system is through a nerve branch from the facial artery, which enters the submaxillar ganglion, through the chorda tympani and also the otic ganglion from a branch arising from the plexus of the middle meningeal artery."

Burchard believes that the nerve supply of the pulp is from the branches of the dental trunks proper, though admitting that nerves pass over the alveolar rim into the pericementum. In mature teeth, he is not certain as to the point of entry. But in a figure showing a cuspid tooth at 13 years, the nerves one-third of the way up the canal are seen to consist of several bundles of medullated fibers which follow the course of the main blood vessels, splitting into fibrillæ, beneath the layer of odontoblasts with which they have a doubtful relationship.

Black states that nerve bundles distributed to the apical pericementum, as well as to the pulp, have a common origin, namely, the inferior dental nerve in the lower jaw and that in the upper jaw, blood vessels and nerves together penetrate the antral wall "into channels of the basal portion of the alveolar bone."

In conclusion, let us note the great diversity of opinions prevailing among histologists. Are not these questions of vital importance before we can in any way reliably attempt or even venture to cure the pathologic conditions brought to our notice? How much more important is the histology, embryology, bacteriology and pathology of the dental tissues compared to the subject of physics by lectures and laboratory as is now being put in the fourth year of some of our dental colleges when it really belongs to the elementary chemic course. Let us encourage workers to give some time, optional or obligatory, during the senior or post-graduate year and give them better facilities by money grants through the Association whose committee on special research could determine whether the candidate was worthy of support or not and let the papers be published in The Journal if worthy of recognition.

METHODS IN THE PREPARATION OF TEETH.[*]

MARTHA ANDERSON, M.D.
MOLINE, ILL.

In preparing sections of teeth for the microscope it is necessary to proceed in different ways according to the structures desired to be demonstrated. For convenience the methods may be divided into: 1, ground or hard methods; 2, injection methods, and 3, structural methods; the structural being subdivided into general or those used to demonstrate cellular structures, and special or those demonstrating nervous tissues.

The hard or ground method should be used for studying tooth tissues in situ. The different processes, though differing somewhat in technique, all consist in grinding down sections of teeth thin enough to examine under the microscope and then polishing to a smooth surface and mounting in Canada balsam.

HARD METHODS.

Nealey's.—Fresh tissues only should be used and the method is a rapid one, the sections being ready to mount in thirty minutes. First one side of the tooth and then the other is ground on a dental lathe with a set of emery wheels. The advantages of this method are that the sections do not curl or become brittle.

---

[*] Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul. Minn., June 4-7, 1901.

White's.—Sections of teeth are ground between two plates of ground glass with water and pumice powder and finished with ground glass alone. They are mounted in Canada balsam without heat; or, they may be soaked in ether twenty-four hours, transferred to thin collodion and stained with fuchsin two or three days, when they are hardened in methyl alcohol and ground down at leisure with ground glass and water only.

Dunkerley's.—Sections are cut off by means of a thin copper disc fitted to a dental lathe and revolving in a trough containing water and fine corundum powder. They are ground on copper discs and a Water-of-Ayr stone.

Cowardine's.—From green teeth preserved in turpentine rough sections are made, and then embedded in balsam and ground with corundum of four grades successively. They are then polished with the finest powder, stone lap, dry whiting powder and the hand; and then mounted in balsam, or dry.

Koch's.—Objects are soaked in copal solution, dried, hardened and cemented to a slide, on which they are ground down on a grindstone and on a hone to the requisite thinness and polished and mounted in balsam.

Weil's.—Tooth is extracted and immediately put into alcohol or aqueous solution of bichlorid of mercury to prevent shrinking. In all manipulations—cutting, sawing, grinding, sectioning—care should be taken that the tooth is at no moment without excess of moisture. Pulp is exposed at both ends and fixed in a saturated solution of bichlorid of mercury eight to twelve hours, washed in water two hours, then harden in dilute alcohol and gradually increase the strength 30 per cent. eight to twelve hours; 50 per cent. eight to twelve hours; 70 per cent. eight to twelve hours; 90 per cent. to which tincture of iodin 1.5 to 2 per cent. has been added. Stain in borax-carmin. Wash, dehydrate, clear, embed in balsam and rub down.

McQuillen attaches sections to a slide with balsam and grinds with a hone.

Latimer grinds on a corundum wheel, an Arkansas wheel, then polishes by rubbing on a smooth and dry plate glass.

Boedecker's.—A fresh tooth, or one soaked for a short time in chromic acid, is sliced thin under water and ground as thin as possible upon the corundum wheel of a lathe, always being kept under water. The sections are then placed in chromic acid one-half of 1 per cent, or picric acid saturated aqueous solution to harden tissues and dissolve the lime salts. They are then stained and mounted.

Hart.—After grinding sections thin, immerse them in 6 per cent. glacial acetic acid and then treat them in the usual way.

Modifications of these methods have been advised, as those of Smith, Röse, and others.

INJECTION METHODS.

To demonstrate the blood supply injection methods are necessary. The blood-vessels are filled with colored substances for the purpose of showing their relations to, and course through the tissues. Beale's Prussian blue is the solution usually used. This mass runs well and has not much tendency to exude from cut vessels. Its formula is as follows:

℞.	Price's glycerin	℥ii
	Tincture sesquichlorid of iron	gtt. x
	Potassium ferrocyanid	gr. iii
	Hydrochloric acid (strong)	gtt. iii
	Distilled water	℥i

Fearnley introduces Carter's carmin into the aorta of an animal, during which time it is kept warm. After the injection it is removed to cold water:

℞.	Carmin	m. cxx
	Glacial acetic acid	m. lxxxvi
	Gelatin solution (1.6)	℥ii
	Distilled water	℥iss

Whitman, in injecting, uses the femoral, or, if that is too small, the carotid or aorta. The animal is immersed in warm water and normal salt solution forced through the vessels to wash out the blood and dilate the vessels, and then the starch injection mass is forced through.

Inj. Mass:			
℞.	Dry starch	1	
	Chloral hyd. 2.5 aq. sol	1	
	Alcohol		25
	Color		25
Color:			
	Dry color (ultramarine)	1	
	Glycerin	1	
	Alcohol, 95 per cent	1	

Lepkowsky injects Berlin blue and then hardens the tissues *in situ* in formol 50 per cent. for two days. Then he decalcifies in nitric acid 10 per cent. (eight to fourteen days) and mounts in celloidin.

Huber used Ehrlich's methylene-blue *intra vitam* method. After forcing through a normal salt solution, methylene-blue in normal salt solution was injected through the carotid until the lips assumed a deep-blue color. Thirty minutes later the lower jaw was removed and cleansed with a dry cloth. The teeth were removed and the pulp placed on a slide in normal salt solution. In a few moments the characteristic blue color was found to have developed in the axis cylinders of the peripheral nerves. In fresh preparations the axis cylinders stained deep blue; the other tissues not at all or faintly. Unfortunately, preparations prepared thus always fade unless a fixative is used promptly. As a fixative a saturated aqueous solution of ammonium picrate (Dogiel). or a solution of ammonium molybdate (Bethe) may be used. The former preparations are mounted in a mixture of glycerole and the ammonium picrate solution; the latter dehydrated and mounted in balsam. Prepared in this way the tissues become so clear that a small pulp may be examined *in toto*. These methods Huber used in a rabbit; they can not be employed in pulps of human teeth.

With these two methods, the hard and the injection, I have had but little experience, having worked mainly with pulps and decalcification of teeth. To demonstrate tissue structures it is necessary to stain microtome sections with different dyes to bring out the different tissues. Either pulps themselves are used, or decalcification of the hard structures is necessary.

DECALCIFICATION METHODS.

Hopewell Smith decalcifies in 5 per cent. chromic acid, or, after hardening in Müller's fluid three to four weeks, removes to alcohol ten to twenty days, washes, seals the apical foramen with collodion and places in 12 c.c. hydrochloric acid 10 per cent. for fifteen hours, then adds 1.5 c.c. nitric acid and in forty hours 1.5 c.c. nitric acid again. In seventy-five to eighty hours they are washed in lithium carbonate for half an hour and cut by freezing method, celloidin, or paraffin. If the freezing method is used they should be dehydrated in 30, 70, 90 per cent. and absolute alcohols successively for one minute each to prevent shrinking.

Lepkowski's.—Pieces 0.5 m.m. thick are placed in pure formic acid 3 parts, and 1 per cent. aq. sol. gold chlorid 6 parts, for twenty-four hours. Then they are washed in distilled water and placed in gum arabic and glycerin for twenty-four hours, washed, and embedded in celloidin or paraffin.

Kleinenberg's formula:	
Picric acid	100
Sulphuric acid, strong	2
Filter and add dist. water	300
Ebner's formula:	
Hydrochloric acid	1
Sodium chlorid	10
Dist. water, ad	100
Haugh's formula:	
Phloroglucin	1
Nitric acid	*10*
Dist. water	50

After this solution, tissues stain well and all elements except blood are well preserved.

Schaeffer used a saturated aqueous solution of picric acid containing 2 per cent. hydrochloric acid and a crystal of picric acid added from time to time. When soft the tissues were placed in alcohol containing lithium carbonate. The alcohol should be changed till no color comes away. Embed in paraffin.

Squire's.—Hydrochloric acid 5 grams, and glycerin 95 grams. It softens slowly and does not interfere with structure.

Huber hardens with Müller's fluid for several weeks and then transfers to equal parts of nitric acid 10 per cent. and hydrochloric acid 1 per cent.

Boedecker advised chromic acid .5 to 1 per cent., used in large quantity and renewed frequently. To enforce the action of the fluid he added a small quantity of dilute hydrochloric acid (1 to 2 gtt.). This is a good method for softening the teeth when still in the jaw. It can be stained with carmin, logwood, or gold chlorid. If gold is used, wash well in distilled water to free from alcohol before placing in gold solution (0.5 per cent.), stain one-half to one hour, thoroughly wash in distilled water and expose to daylight several days.

Lactic acid acts well upon teeth (if diluted sufficiently) by dissolving the lime salts much faster than the chromic acid. Specimens decalcified in lactic acid are not distinct enough for study with high powers, hence after being softened with lactic they must be placed in chromic for several weeks.

Boll advises chromic acid one-thirty-second per cent. and gradually increased in strength until in two weeks it contains 2 per cent. or over. Decalcify five to six weeks.

Hopewell Smith.—For jaws of embryo mammals, strip jaws of all tissue except the gums, wash in normal salt solution and place in Müller's fluid for two weeks. Change often, and remove to alcohol and cut by freezing microtome, celloidin or paraffin. Its advantages are its simplicity, the odontoblasts are a large size, and the formation of the dentinal fibrils are at their highest stage of development. It affects but little the relative positions of dentine, odontoblasts, and pulp.

In using the tooth pulps alone great care must be exercised in obtaining them that the pulp may be obtained in its entirety. While some workers claim that all that is necessary is to crack open the tooth and lift the loose pulp out. my experience leads me to think differently. Many pulps that I have worked with have had small pieces of dentine attached along the sides. These were unnoticed at first until the knife struck them in microtoming.

In some sections the tomes could be seen extending out from the odontoblasts along the free border of the section; in others these were present only in places, and many were perfectly free from them. Some investigators believe that the nerve fibrils pass up between the odontoblasts and enter the dental canaliculi side by side with the dentinal fibers. Others differ; but whether so or not one thing is certain, that there is an intimate connection between the tomes and the dentine and that, being so delicate, great care is necessary in handling them. Boll claims that the odontoblasts, by their long processes, which extend into the dentinal canaliculi, are held firmly to the inner surface of the dentine, appearing to the naked eye as a thin mucus-like film. If this film is scraped off with a knife and brought under the microscope we see besides peripheral cells some parts of the inner pulp tissue. He therefore advises splitting a tooth and placing pulp and tooth in a very weak solution, chromic acid one thirty-second per cent. for one hour. Remove the loose fragments of tooth with a thin sharp knife; go between pulp and dentine close to the walls of the pulp cavity. In specimens obtained, thus large quantities of non-medullated nerve fibers are seen toward the periphery of the pulp which, when removed in the ordinary way, adhere to the pulp chamber.

Robertson holds that when a tooth is broken open the odontoblasts cling to the dentine and the pulp remains free, thus proving that the attachment to dentine is stronger.

For ordinary staining, logwood, logwood and eosin, and Van Giesen are good stains; but for special staining, and especially for the nervous tissues which we are so anxious to bring out, special stains are necessary. Of these the following are largely used: Golgi's stain for demonstrating nerves; Ehrlich's methylene-blue shows axis cylinders of peripheral nerves; Apathy's double stain for differentiating nervous and connective tissues; Mummery's iron and tannin for fine nerve fibers; Marchi's medullated nerve fibers, and Underwood's gold chlorid.

For the odontoblasts place in 6 per cent. solution of potassium anhydrochromate for twenty-four hours and tease in picro-carmin. To demonstrate the nerves in the processes of the odontoblasts, Beale crushes a fresh tooth and stains by his method. He macerates in strong syrup until soft and examines a few very thin sections, when the acid will be found to render all tissues transparent except the nerves which are granular.

SYMPOSIUM ON DEGENERACY OF THE PULP—PAPERS OF DRS. TALBOT, LATHAM AND ANDERSON.

DR. R. R. ANDREWS, Cambridge, Mass.—Concerning the matter of preparing tissue, I have tried all these various complicated methods and with more or less success, but I finally came to the conclusion that if I got my tissue as nearly alive as possible, and used the simplest possible means of preparing it, I got in every case the better results. I have worked mostly on the heads of calves because it seemed to me they showed the tissue so well. I have taken the calf at birth and taken out the teeth and transferred them to a low percentage of chromic acid solution, 0.5 per cent., and if necessary I would use some stronger acids, hydrochloric, for instance, a very small percentage; I cannot tell just exactly the combination which I used. I placed that tissue in the solution and tested it from day to day. I have let it remain three or four weeks, but as soon as I found the area of that tooth sufficiently softened to use the microtome, I would let it remain until my microtome reached hard tissue, and in that way I found the most beautiful photographs could be made from the higher powers. Many pictures of low powers are entirely useless with the higher powers. The tissues seem to have run together and there is no definite picture and no differentiation of the pictures. They have to be very carefully prepared and it takes a long time. I have always been in favor of working as near life as possible, soon after the preparation was taken from the live body and in the simplest possible way.

DR. G. V. I. BROWN, Milwaukee, Wis.—I would have liked to see the symposium develop along the line of pathologic changes that occur in the pulp, so that under the microscope some definite etiological idea could be arrived at. I have had a great many interesting cases the past year, but in a large measure the benefit of them has been lost, because in our laboratories in Milwaukee we do not seem to have any distinguishing way of arriving definitely at the pathologic changes that take place in the pulp tissue. I have in mind one case in which there was a spasmodic affection of the muscles of the face accompanied by a recurrent pain which occurred at intervals of one and one-half to two minutes, so severe that the life of the patient was almost unendurable and the hyperesthesia at the posterior portion of the mouth and pharynx made it almost impossible to take nourishment. The difficulty was finally located in the tooth pulp and cured, and although that pulp was carefully preserved and an attempt made to treat it so it would show the characteristics of that condition we were unable to arrive at anything which we felt we could give out as scientifically correct.

DR. R. R. ANDREWS—If Dr. Talbot, in the large number of teeth he examined, had made a pathologic study of them, it might have been of great benefit in this direction, and he would have found that the pulp even at full maturity of the tooth is of great service. It is a mistake to suppose that the pulp has lost its function when it is fully formed. I know it is the belief that when teeth are fully formed the pulp might as well be out and they let it go, but those who have studied this subject will tell you that a healthy dental pulp has a function to perform through life.

DR. EUGENE S. TALBOT, Chicago—I scarcely think the Chairman and Dr. Brown have quite grasped the situation in regard to these papers. The general subject of this symposium is "Preliminary Work." The teeth were selected by myself and taken at all stages by men who make a specialty of the extraction of teeth. Age was not hence taken into consideration in a general way. The object of the paper was to give my own results only. Dr. Latham, Dr. Anderson and myself have undertaken a large amount of work, which is all preliminary. We have undertaken it in a systematic manner, taking up the general conditions of the teeth in a healthy state and from embryologic and nosologic points of view. There is one point in dental literature to which attention was paid, giving credit to whom credit is due. One object of these papers is to summarize the literature. One-half of it was given. The idea is to compile all literature upon the pulp before generalizing. That has been my method throughout life. All my writings show that I feel obliged to give credit to those that have done work before. After that, I take up the line of work and in all points where the work corresponds with that previously done, I give credit. If it differs, I show wherein difference occurs. That is the only way in which to make scientific research.

DR. VIDA A. LATHAM, Rogers Park, Ill.—I would like to say that I am in the center of a large city, but I have had extreme difficulty in getting hold of material. Our library boasts of a medical department, but it is almost devoid of dental literature except a few current journals. I believe the Northwestern Dental School has a library, but it is rather difficult to gain access, and then, when used for their students, the papers are either in Swedish or Hungarian and I am ignorant of those languages. I have tried to be pretty careful in regard to finding the original, and I have found papers that were under men's names that were a little familiar, that when carefully searched they were not their work at all. So I have tried to be particular on this point. It is rather difficult to follow the literature. I have used the excellent *Cosmos* index; also Dr. Taft's index, which is very good, and in that way I hope I have not missed any good articles in the journals, but I would be glad to hear of any other good papers that have been published.

There is another point in pulp methods that Dr. Anderson has brought out. I have tried to use simple methods. I believe the only successful methods that are being used are those which take in the jaw itself. It is almost useless to take out the tooth because you break the pulp and the continuity is broken. It is difficult to get a jaw or teeth from the human unless you are attached to a hospital. There is a prejudice in America against the postmortem; it is almost impossible to get teeth *in situ*. A point that strikes me very forcibly is why should we use the term "degenerate" in the embryo? Take the new works on embryology, take the American Dental works; take any standard works, and you find almost nothing on normal, let alone, degenerate pulp; the name does not occur. When we think of the importance of it, when the literature is silent on it, how can we treat sensitive dentine? Why should we take out the pulp? How can we treat the pulp when we do not know what it is? It is impossible. Out of ten pulps, nine are probably pathologic. Those who do dental histologic work use the ordinary methods for tissues. These methods must be studied especially with relation to dental tissues. Dr. Andrews is also very fond of glycerol, but after a few years the specimens may disappear! Specimens that I mounted ten years ago, I can find no trace of, and under those conditions, I feel a little doubtful about using glycerol. A man may write asking if you have certain slides to prove your statements, and therefore you must keep the specimens. I once wrote to Dr. Sudduth for specimens and he replied that he did not keep his slides as they were so easy to make! Personally, I do not agree with him. I have put in six months on one slide and then had difficulty to secure a good specimen. This, I beg to say, is mostly preliminary work, and now we expect to go further with various animals and human material from the embryo and find out where the pulp comes from, and when it originates. Some say it forms the odontoblasts, and some say it does not. If sensitive dentine exists there must probably be sensory nerves; if a formative organ they may be secretory cells like enamel or ameloblasts, and I believe nervous also, because we now are finding nerve endings in the epithelium in the tongue, cornea and all parts of the body due to the newer and special methods now being introduced, which previously have not been seen.

DR. G. V. I. BROWN—I am glad to hear what Dr. Latham has said and glad to hear the statement about the preparation of specimens. So far as I have tried the work it has been unsatisfactory. A large proportion of the methods are comparatively useless in application. It is one thing to get a nice, healthy specimen, and another thing to get a reasonable effect in demonstration, and then you should have a perfect specimen.

DR. R. R. ANDREWS—In regard to Morgenthau's demonstration, I think he uses the Galbia method. He found the dentinal tubules which appear to be fibers of nerve structures. I worked on that method for more than six months trying to get some results, with entirely negative results and I used the most careful methods. It shows how difficult it is to get at these things.

PERIODS OF STRESS AND THEIR DENTAL MARKS.*

JAMES G. KIERNAN, M.D.
Fellow of the Chicago Academy of Medicine; Foreign Associate Member French Medico-Psychological Association.
CHICAGO.

Despite embryologic teachings, that old notion that man is an entity who undergoes development alone, still controls pathology and physiology. The human being, however, is a compound animal in whom organs have their own nervous system and their own life under control of the cerebrospinal system. The child is not an undeveloped man, but man is an imperfectly developed child. The embryo has to contend with retrogressive as well as progressive factors, and the same is true of man after birth. Vertebrate embryos are of common type at their origin and assume successively many common forms before definitely differentiating. The higher vertebrates contain in essence the organs and possibilities of all lower vertebrates. The human organism is therefore a balance. While the balance is maintained the organs work in unity, though there is a constant struggle for existence between them. During embryonic existence this struggle is more intense and diversified than after maturity, because of the influence of three contending forces: remote atavism or throw-back to primitive types, immediate atavism or throw-back to less remote ancestors of the same type, and finally immediate heredity. Remote atavism tends to preserve structures which occur in the normal embryo only to disappear. The human heart passes through all vertebrate heart phases. This is likewise true of the teeth During the life of the embryo the tooth system wavers at one time between the polyphyodont and the diphyodont. At this period, should the diphyodont tendency of man be arrested, the polyphyodont takes its place and the human being sheds teeth as do reptiles. On the other hand, should immediate atavism gain the ascendancy over remote atavism shown in polyphyodontia, diphyodontia occurs. When the struggle for existence between the two is keenest a period of stress results, which affects the organism as a whole. This stress expresses itself most strongly in dental and maxillary irregularities, since the jaws and teeth are among the most variable structures in evolution. Under what is known as the law of economy of growth is governed the relation of the organs to each other, and the process whereby one structure is sacrificed for the development of another or for the development of the organism as a whole. Since certain parts in the evolution of organs disappear and in the evolution of organisms certain organs through suppressive economy and since the disappearing and developing tendency of necessity centers around the time when certain functions are to be lost by the disappearing and others gained by the developing, periods of stress occur around which the law of economy of growth centers the struggle for existence between parts of organs and between organs themselves. It is because of this that physiologic atrophies and hypertrophies and their reverse occur. Nearly all conditions of physiologic disturbance may result at these periods of stress under the influence of maternal environment or of hereditary factors. The fetus, therefore, must be prepared to pass through not only intra-uterine periods of stress, whose dental mark has already been indicated, but post-uterine periods as well.

The child has not attained its full development at the time of birth. It has within it certain potentialities, some of which are never fully realized. There is a constant struggle between the central nervous system and certain bodily functions for preservation of the individual and for preservation of the race, through which the central nervous system fails to reach the height indicated in the child. This struggle for existence after birth is keenest at certain periods. Each period is marked by dental phenomena. The first is the period of the first dentition. Here, coincident with teething, the child is gaining its impressions of the outside world, is learning to walk and talk, and is also developing its eliminative organs, especially the rectum. These varied functions constitute a strain on the system, effects of which are most often evinced through the teeth and jaws. The conditions charged to teething are an expression of constitutional strain finding its outlet through the point of least resistance. During this first dentition, the strain of development forces attention to the teeth, and thereby leads to neglect of other factors. The teeth at this period should be regarded as a meter of constitutional strain, and not a cause of it. Within the next period, between 2 and 6, occurs the first great check to continued development of the brain. Man has learned to use his brain despite this check, but had it not occurred he would have had a higher type of brain to use. Sometimes during this period the brain gains in size, albeit not in balance, at the expense of the general system. In no small degree the struggle for existence during this period of stress centers around the development and eruption of the 6th year molar. With the eruption of this molar, premature puberty, sexual precocity, epilepsy, insanity, gout, rheumatism, obesity, and other nutritive degeneracies, may occur. All have been charged to the eruption of the 6th year molar, whereas its irregular or difficult eruption is, like them, an expression of constitutional stress. Hygiene of the teeth at this period means also constitutional, mental and moral hygiene. Epilepsy, for example, is not a disease, but a symptom of weakness of certain vasomotor inhibitions. The first convulsion does not constitute epilepsy. Through a law of the nervous system, nerve action once roused tends to repeat itself. In this way are established normal and abnormal habits, of which last epilepsy is one. In its early stages a habit normal or abnormal is easily checked. The first convulsion, therefore, could be prevented were its premonitions known. A recurrence could also be prevented were the constitutional origin recognized. Observation of the general constitution at this time, because of irregular eruption of the 6th year molar, would enable the physician to nip epilepsy, and many other allied conditions, in the bud. Reflex notions, however, must be flung overboard. All irritations should be removed and any constitutional irregularity treated.

The obese child of 6 years, even though the obesity be not excessive, should be looked upon from a health standpoint with suspicion. There is liability to disease, and marked tendency to systemic weakness when under morbid influence. These children are particularly liable to rheumatism, gout, etc., and profuse hemorrhage from slight causes. Youthful obesity is sometimes associated with precocious maturity and resultant early senescence. More often it co-exists with extended infantilism, as in the case of Dickens' "fat boy."

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

E. S. Talbot, examining 267 corpulent school children and adolescents, found marked stigmata of degeneracy. Ninety-two per cent. had deformed ears to a marked degree. Sixty-six per cent. had arrested development, as compared with their age, while 12 per cent. presented excessive development. Thirty-four were too young to determine the form and size of the jaw. In 33.5 per cent. of the thirty-four the molars, incisors, cuspids and bicuspids were present. Ninety-six per cent. of these had small teeth. Eighty-seven per cent. (of the 233) had arrested development of the upper jaw; 22 per cent. arrest of lower jaw. Sixty-four per cent. had V-shaped or saddle-shaped arches, or their modification, and protruding teeth. Seventeen per cent. had hypertrophy of the alveolar process. Eighty-three per cent. had small teeth. Twenty-seven per cent. had extra tubercles upon the molars. Eighty-two per cent. had stenosis of the nasal cavity more or less marked. Thirty-six per cent. had deflection of the nasal septum to the left and 29 per cent. to the right. Twenty-one per cent. wore glasses for eye defect. In 58 per cent. there was enlargement of the thyroid gland, and in 7 per cent. arrest of development of it. In 296 cases of early lipomatosis (180 male and 116 females) coming under my own observation, there were 10 cryptorchids, 6 hypospadiacs and 3 cases of pseudo-hermaphroditism. Three females had infantile bifid uteri. Four had enlarged clitorides; in one of these the urethra perforated the clitoris, as in the female shrew. Of 40 girls who had reached 18, only 3 had menstruated normally. The others were amenorrheic or dysmenorrheic, or had neurotic storms during the period. There were 160 hebephreniacs among the number. Of these 120 had masturbated excessively. Ten had been nymphomaniac or satyriasic, the sexual appetite having become completely extinct at 18. Fifty of the non-hebephreniacs never showed any signs of sexual appetite. Three of the hebephreniacs were sexual inverts, while 80 practiced various perversities. Of the non-hebephreniacs 10 were cyclothymiacs, 30 had acute forms of insanity, 10 were epileptic and 15 hysteric. Thirteen had had chorea. Ninety-seven had difficulty in learning to speak and 30 always stuttered.

The appearance of the first permanent molar is therefore of great significance to stomatologist and sociologist alike. The mental and moral deficiencies usually present will interfere with proper care of the teeth particularly indicated in cases where such deficiencies occur. While the eye has received much attention as a sociologic guide the teeth and jaws have, as a rule, been much neglected, although of even more significance than the functional disorders of the eye.

The next important period of stress is practically that of the second dentition. Here there is a foreshadowing of the mental and nervous phenomena of the following period of stress. Sexual development now frequently receives its initiative. What is true of neuropathic children earlier is true at this time of ordinary children, under conditions of stress. There is irregularity of disturbed sleep, irritability, apprehension, strange ideas, great sensitiveness to external impressions, high temperature, delirium, convulsions from slight causes, disagreeably anxious dreams, romancing, intense feeling, periodic headache, muscular twitching, capricious appetite and marked intolerance of stimulants and narcotics. The struggle for existence between the developing alimentary and other systems between the 2d and 6th year had produced effects which are most felt during the 6th to 12th year. Provided this struggle is between normal limits, the average child does not incur permanent danger from it. If, however, from heredity, congenital defect or improper environment, development of the system does not proceed equably, then strain results, which produces, during this period, not only the conditions already described, but the following as well:

NEUROSES.

Convulsions.
Nervous laughs
Nervous coughs
Hiccoughs
Renal
Hepatic
Gastric
Vesical
Genital
Pulmonary
Adenopathic
Cardiac
Metabolic
Stuttering
"Tics"
Neuralgias
Neurasthenia
Ecstasy
Hysteria
Chorea
Epilepsy
Somnambulism

PSYCHIC TYPES.

Hallucinations
Anomalies of character
Aberrant sentiments
  Love
  Jealousy
  Anger
Obsessions or imperative concepts
  Pure
  Attended by impulsive acts
    Arson
    Suicide
    Homicide
    Alcoholism
    Theft
    Rape
    Non-criminal acts
Night terrors
Idiocy
Imbecility
Mania
Acute confusional insanity
Melancholia
Transitory frenzy
Stuporous insanity
Stupor
Katatonia
Paranoia
Cyclothymia

These are apt to occur at this time as a reaction to temporary disturbances of health. The temperature at which psychic disturbances begins in a child is a fair index of its brain stability. Neuropathic children, on a very slight rise in temperature or even without it, are subject to attacks of unreasonable elevation, during which they are quite beside themselves, rushing about wildly, shouting, fighting, and without clear consciousness of their surroundings. With this last picture stomatologists are very familiar in children brought to them for care of the teeth. During this period such disturbances have to be taken into account in cases where maxillary and dental treatment and regulation are indicated.

The period of puberty should include the period from the appearance of the menses or spermatozoa until the completion of the 25th year. The appearance of the wisdom tooth at this time marks human maturity, which was the reason that 25 was selected for the age of maturity by the code of Napoleon. During this period it is possible to correct dental and maxillary irregularities with benefit to the subject. Every one of the conditions enumerated are due to strain during the period between 6 and 12 may appear. In addition there occurs a type of mental disorder called hebephrenia, or insanity of puberty, which is practically incurable after its development. This is an insanity peculiarly charged to cigarette-smoking, masturbation, overstudy, religious excitement, and "love," all of which are the expressions of the defects and not their cause. These subjects in the earlier stage of their psychosis peculiarly require teeth regulation. In some cases, strain from the tooth irregularity may have sufficed to upset the unstable mental balance. The next great periods of stress in human life are those of the climacteric and of the senile period. The first is accompanied by the menopause in women and prostate change in men. The dental conditions marking these two periods of stress are generally involutional in character and require prothesis or treatment, not correction.

DISCUSSION.

Dr. Eugene S. Talbot, Chicago—I have been interested in this subject for years and I have spent a great many years in the study of these conditions. I have never heard a paper so clearly define those conditions as the one that has just been read. Someone has said that the discussion of dental subjects has been exhausted, but a knowledge of the conditions of the mouth so far as hereditary environment and embryology are concerned is still in its infancy. There are some points which deserve attention. Dentists often remark that if their patients were more careful with their teeth they would not decay, and then prescribe a course of treatment handed down for decades. The same old story is told of brushing the teeth, recommending the use of certain preparations, etc. As Dr. Kiernan said, evolution of the teeth is tending towards extinction. Decay of the teeth is a natural process and all the treatment on earth —as now applied—will not save them except in the individual. It is not only a personal calamity, but it has become a national one. Study of the teeth and jaws of the peoples of Europe shows teeth of men deteriorating, where the peoples are not of a nervous tendency, as they are in other countries. Through Greece, Turkey, Russia, Norway, Sweden, France and England, in the order mentioned, is evident degeneracy of the jaws and teeth. There are no peoples in the world whose teeth are decaying to-day like those of the English people. There are no irregularities of the teeth like those of the English. In England it has become a national calamity and the authorities have appointed committees and have furnished money to investigate the cause of decay of the teeth. All attention, the best methods of treatment will not save them.

Another question of the jaws and teeth that Dr. Kiernan has discussed, is the evolution of the second set of teeth. Dentists think they are able to treat pyorrhea alveolaris or gingivitis, and some claim to cure every case. With them it is simply a matter of local application, a peculiar sense of touch with instruments to remove all visible deposits. The condition is an atavistic one, and the disease is preventive to a certain extent. Still, should the individual live long enough, he would lose his teeth. This is a process of osteomalacia and nothing more than atavistic. As Dr. Kiernan has said, change of the teeth is going on continually. Where one tooth is shed in the lower vertebrates after it has done its duty, another takes its place. Where the temporary teeth are shed by absorption the second set takes its place. This absorption goes on with the second set and the teeth are lost in time. This occurs not in all cases, however, but in the majority, if the person lives long enough. Dr. Kiernan showed you a picture of the degeneracy and arrest of development. This is a picture where the child has grown to manhood, yet remained arrested in development. If the internal structures of the body were examined arrest of development would be evident. All have seen such cases, since they are very common. This particular condition illustrated, has arrest of development of the jaws and face. Dr. Kiernan remarks that structures that are temporary are changing from generation to generation.

For this reason dentists should be careful in regulating teeth, especially in children of from one to twelve years of age. These children are in the condition shown. In this neurotic condition the nervous system is very easily involved and also other organs of the body. Children are often invalided for years by having their teeth regulated and dentists should be very careful on that point. Another point about regulating teeth in such patients needs attention. Dentists can not tell just exactly how it comes about, but where the teeth are moved by springs, ligatures and all kinds of appliances, they can not be held perfectly firm. Later in life absorption of the alveolar process occurs at this very point, due to osteomalacia or alveolar absorption. Later in life gingivitis sets in from regulation of the teeth, the jaws are never restored to health and the absorption goes on until the teeth become loose and are lost.

I want to call your attention to the picture, a four and one-half months old embryo. All have seen children that have the appearance of age, with little hairs upon the face and ears, with wrinkles in the face, the hair frequently gray in spots, the skin drawn up and the fingers long and slender. In such patients, dentists should be very careful in the regulation of the teeth and in all operations. They always have irregularities and the greatest care is necessary because of the unbalanced nervous system.

Dr. Vida A. Latham, Rogers Park, Ill.—It is a good thing to have the tension made clear on pathologic principles. Many teachers have made the statement that it is absurd to suppose that the changes are made through the nerve functions. They can occur through tension, perhaps not permanently, but it is one of the factors underlying this development, or it may be through a case of retrogression. When we think of the enormous amount of force that goes on in the development of the teeth coming through four dental cycles, and of the congestion which involves the vasomotor and vasoconstrictor systems, we may come to the conclusion that it is due to the period of first stress. I have heard men advance the argument that pathologic stress is absurd; that it can not come from such a source, and was only a poor excuse for ignorance of some local condition.

Dr. G. V. I. Brown, Milwaukee—I can not say very much on this subject without encroaching on the paper that I expect to read later on. I shall be obliged to disagree with Dr. Talbot concerning the regulation of teeth, because I have to begin to regulate the teeth of these young patients before they are entirely destroyed, and from all of which I have demonstrated I can not agree with him. In regard to what he says of the disastrous results following the regulation of teeth in children and young persons, I think it was rather the fault of the method than the age of the patient, and I am convinced that where that continual absorption went on it was due to the effect of occlusion of the jaws on account of malposition, which caused an irritation of the tissue around the mouth.

Dr. James G. Kiernan, Chicago—I only wish to correct a little terminology which I think might be desirable in this Section. There is perhaps no word so misused and misleading as "degeneracy." The question is whether there is general degeneracy or whether it is a disappearance of certain parts for the benefit of the organism as a whole. It is true, a great many changes occur in this way for the benefit of the organism as a whole. The teeth are decreasing in number. There is very good reason to believe that man at one time possessed at least two extra incisors. There is also very good reason for believing that the wisdom tooth is tending to disappear. There is also good reason to believe that the human tooth is becoming microdont rather than macrodont, rather smaller than larger. This is along the general line of evolution with reference to the face and jaws. The human jaw itself with all its beauty, the human face, with all its beauty, is degenerate. For biting purposes and chewing purposes, it is not as valuable as the jowl of the lower races. It is an embryonic feature. It has lost space for the benefit of the brain. The brain has been absorbing more and more space at the expense of the bones of the face. Therefore, in dealing with this question of irregularities it would be wise to look at it in certain cases as a normal process. In certain cases it is wise to study the teeth not only from the point of regulation, but also from the standpoint of removal a little more than is done. No human hand can turn back the clock of time, retain a high type of man, and yet restore the jaw of a prehistoric ancestor who lived on food in which there was an enormous waste. The native or prehistoric races had beautiful teeth; but those teeth could not exist with the environment of the civilized races.

Civilized man does not waste his food so much; he does not need to do so much chewing and tearing. In the only animal that can be compared with man, the dog, similar changes are taking place, and these changes of domesticity are coincident with the changes occurring in civilized man. Another factor also influences these changes. There are many race types with different jaws and different teeth. No races are pure considered from this standpoint, but all races are intermixed. It is safe to say that every one of the English-speaking races has some primitive race element in them. Every one of the Teutonic races and every one of the Eur-African races have the same elements in them, and also the Eur-Asiatic. These races have different types of jaws, different sizes of teeth; from their mixture comes the so-called Aryan race. These people are subjected to a new environment. It is therefore a duty to study how far in one case removal of the teeth in a certain type might be a benefit in correcting irregularity, and how far in the other it might be injurious, and deal with the question from that standpoint. It can not be dealt with in a general way, but the individual conditions to which man is exposed must be studied. There is much nonsense talked about the degeneracy of the teeth. This is usually ascribed to luxury. The degeneracy is often an expression of the advance of the human race. When man gets fewer teeth, then there would not be so much irregularity, nor so much trouble in other directions.

INFECTIOUS DISEASES.*

ALICE M. STEEVES, D.D.S.
CHICAGO, ILL.

A knowledge of the possibility of transferring infectious diseases from one patient to another by means of instruments or otherwise, and of the character of the infection itself, is of the greatest practical value. While the necessity for proper precautions to avoid these accidents has long been recognized, the recent advances in the bacteriology of the mouth and throat cause the subject to assume new importance.

Of all diseases in which the infection is frequently carried from the mouth of one patient to that of another, perhaps the most important is syphilis. In this affection two different lesions are formed in or about the mouth, each characteristic of the disease, and appearing at different periods in its course. The primary sore is frequently to be found upon the lips or within the mouth. This is especially true in children. The mucous patches of the secondary stage are usually seen in the mouth, where their seat is on the inner surface of the lip, the tongue, the palate, or the fauces. In size they are from an eighth to half an inch in diameter, and while they extend superficially they are never deep. They are whitish in color, with rounded edges and raised rather than depressed. These two lesions are the sources of most of the infection, which causes new cases of the disease, the virus being carried by actual contact, surgical instruments, household utensils or other accidental means; and to unaccustomed observers they may be overlooked or neglected, or considered harmless because their true character is not recognized.

The frequency with which these conditions occur and the great danger attached to them should warn every oral surgeon to be ready to recognize them and to take proper precautions to protect himself and others.

Modern research into the bacteriology of the mouth and throat has suggested new possibilities in the matter of carrying infection from patient to patient.

The discovery that the germs of scarlet fever and diphtheria may be found in perfectly healthy mouths and throats, and the fact that these germs remain in the mouth and throat for long periods after the clinical signs of the disease have disappeared, suggests the probability that these diseases may be transferred from patient to patient by unclean instruments. Well proven instances of this kind are indeed rare; yet this mode of infection is worthy of attention.

The germs of diphtheria are sometimes found in tooth cavities or in a healthy throat, and although they may not cause the disease in that individual because of his natural resistance, when carried to the mucous membrane of a susceptible person they may produce the disease in a virulent form. The bacillus of diphtheria may be the cause of all grades of sore throat, from a simple acute catarrh to an intense membranous inflammation extending into the nose and mouth; so that the true nature of a sore throat may not be recognized and the bacilli spread from patient to patient on septic instruments as is so often done by infected spoons and forks.

Diphtheria bacilli usually remain in the throat two weeks after the membrane has disappeared, but have been found five or six weeks afterwards in some cases. The infectious nature of purulent discharges following scarlet fever, such as a rhinitis or pharyngitis, are now fully recognized, so that, if after one of these infectious diseases catarrhal inflammations are present, the necessary precautions can be taken to prevent new cases of the disease.

In the same manner, erysipelas, which begins so often at the juncture of the skin and mucous membrane, and pus cocci from suppurating processes in the mouth may be transferred from patient to patient; and it is easily conceivable that the bacillus of tuberculosis could be taken from the mouth of a tuberculous patient on dental instruments and be deposited in the mouth of another patient and then find its way into the lungs.

DISCUSSION.

DR. VIDA A. LATHAM, Rogers Park, Ill.—This is a subject that is scarcely touched upon by dentists, but in connection with the physician we can accomplish a great deal in this direction. Many cities have a quarantine law, and in that way we can control these diseases in large cities, but it is more difficult where a physician is allowed to use his discretion in placarding a house. There is a great latitude in that method. If a physician is not perfectly honest and upright, he can probably be persuaded by higher fees or some other way to favor the family. A man will tell him that he has got to go to business, and the result is the physician does not quarantine the father of the family, and he goes to the bank or to his business without hindrance.

I have had two horrible cases of infection in little folks through the non-disinfection of instruments, more especially forceps. In one case that was referred to a specialist, a syphilitic lesion was caused in the upper jaw through the use of unclean instruments. In another case a woman contracted primary syphilis and as I did not care to be in a malpractice suit, it was referred to a specialist. The cause was using infected forceps in extracting her teeth.

In dental schools how many students are trained to see cases of syphilis in the oral cavities? They do not see them because they are not pointed out. I have only seen them, because I have practiced medicine and dentistry. Few dental schools make any effort to classify or make a clinic for such diseases. Unquestionably, students ought to study and know these conditions. Most of us, if we should see a case, would not recognize it. Therefore, I hope the teaching of surgical cleanliness will be broader and deeper in all its branches.

DR. GEORGE T. CARPENTER, Chicago—The ordinary practitioner will not recognize the conditions, particularly syphilitic lesions, and it is a very difficult matter, even where he suspects a case, to get a history of the case. Syphilis is a disease that is covered up, and sometimes the only thing the practitioner can do is to pursue syphilitic treatment in a case he suspects and the case will respond if his surmise is correct. We can not be too particular in regard to the absolute importance of sterilizing instruments. Less than a year ago I had a relative in my office who was having a little work done. He spoke of a slight abrasion at the corner of the mouth. I cleansed it and gave it some trivial local treatment and the incident passed from my notice. At the same time, I held the chair of oral surgery in one of our schools. A short time after that a brother, who was a medical student at that time, and who has since graduated, asked me if I had noticed William's mouth. I told him I had not specially noticed it. He said he wished I would notice it, as he himself was a little alarmed. He had been taking one of the preparations of mercury, and he believed he had secondary syphilis. If a person teaching these things will let them pass from under notice, what will the ordinary practitioner do? Consequently, I think we should be alive to the existence of these conditions, but above all we should pay strict attention to the sterilization of our instruments.

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

Dr. A. E. Baldwin, Chicago—The statement is made that cleanliness is next to Godliness, but I believe that cleanliness is Godliness, especially in the dental chair. I think we sometimes exaggerate the importance of the health departments of our large cities in regard to the transmission of many of these diseases. I think it is a question as to whether some of these diseases that are called infectious or contagious are really what the name implies. Where we find those conditions present in healthy mouths, for instance, tubercle bacilli, we find them often present in many mouths of perfectly healthy people. In many school-children we find those bacterial conditions are present in a perfectly healthy mouth. I suppose the only conclusion arrived at is that we must have a proper condition of the system so that the resistance is not great enough to throw off the effect of the systemic poison.

In regard to the use of cleanliness, it seems hardly necessary to speak of it, but I recognize the condition Dr. Carpenter speaks of, the busy practitioner omits to investigate some cases that he would investigate if his mind were not centered upon something else and his time limited. It requires a good deal of courage to acknowledge our shortcomings, but I think if the truth were told by all of us, some things fully as bad or even worse might be said than what the Doctor has told us. But the only thing to do is to fix the fact in our memory, that we must be very careful in everything that tends to the welfare of our patients, and that we must attend to the absolute cleanliness of our instruments, our hands, and our persons.

Dr. James G. Kiernan, Chicago—There is a rather serious error in Dr. Baldwin's statement. In the first place, for infection, two things are necessary; a culture medium for developing the particular germ, as well as the germ. There is probably no healthy individual without pathogenic germs in his mouth. While he is immune under given conditions, those bacteria may be transmitted to another non-immune individual and the result continued indefinitely. The particular medium may be immune, but he continues the danger. That danger, however, has been met somewhat by the prevailing practice in dentistry of using antiseptic washes. There may be certain bacteria in individual mouths and those bacteria may not gain entrance into the system until after operation. This is the case with the streptococcus, the staphylococcus and other pathogenic bacteria. The existence of bacteria in a healthy mouth contains an element of danger greater than is generally recognized.

Dr. Vida A. Latham—I would like to emphasize a point brought out by Dr. Kiernan. I think we doctors and specialists should pay particular attention to the throats of children at school. How many children are allowed out under two weeks with an infectious or contagious disease? In England it is at least six weeks or until all the scabs and rashes have disappeared. Here, from climacteric conditions, measles, scarlatina, etc., would be rather light, but there the mortality is greater. In the case of scarlet fever it may be only a light attack, and the child may be back in school in two weeks! I know of a child who had a light attack of scarlet fever, whose mother allowed it to play with other children, putting kid gloves on the hands of the child. Of course, there is danger of infection. I have a friend, a lady, who went to a house where there was a case of scarlet fever unknowingly until the mother told her that her little girl had the disease and also diphtheria. There was no placard, though under a physician. My friend went home, changed her clothing, then hurried to a dentist's office, where she had an appointment. That is where contagion comes from. I do not think children should be allowed out of quarantine to mingle with people as early as they are in Chicago.

Dr. G. V. I. Brown, Milwaukee—I remember last year a gentleman gave us a very scholarly dissertation upon this subject, and it set me to thinking a good deal. Since then I have tried to do a little missionary work, and during the last year I have given, at various times, before school boards and school committees and any who were interested in the subject, an illustrated discussion on this topic, in which I tried to enforce the value of care in this direction by having slides thrown from the lantern upon the wall, illustrating these different germs that we have been speaking about, particularly the diphtheria bacillus, the pneumococcus, and so on. I do not think I can do better at this time than to emphasize again the necessity of doing something more than talking these things over among ourselves. We all know the danger of infection. We are benefited by having the idea that cleanliness is next to Godliness impressed upon our minds, but if we would resolve ourselves into a committee of the whole, and go out from here and spread the information until we make school boards and those who have charge of the instruction and care of young people recognize the importance of these things, we would be doing a great deal more than we are doing here now. I have tried to make it strong in speaking of diphtheria by calling attention to the fact that Park View had an epidemic of diphtheria, and at least 1 per cent. of the children had these germs in the mouth. In Milwaukee we have had members of the medical profession, during an epidemic, examine the mouths and throats of children every morning before school began, but it seems to me that is a good deal like locking the barn door after the horse is stolen, because by the time the lesion is manifest, or the disease recognized, the child has already exposed more children than it would be possible for us to compute. The same is true, in a large measure, of tuberculosis. If one in every seven dies of tuberculosis, as has been stated by Dr. Senn, and many agree with him on that point, and the disease is so prevalent that it defies all our laws of sanitation, it seems to me the practical thing to do is to begin right in the mouth. In by far the majority of those cases of affections of the lungs, the bacilli are in the mouths of such people continually, and whatever care may be taken of the sputum of such people after it leaves the mouth, a little care taken before it leaves the mouth would be much better. It is a simple matter for public schools to have a large vessel at the door with some cheap antiseptic, and make it obligatory upon pupils to rinse their mouths before entering the schoolroom. I am certain we would do more to check diphtheria and influenza by checking these things than we can in any other way. I think it is well worth continually repeating until we are tired of it, or until we finally make the right impression upon the minds of the people in charge of our public institutions. We are not politicians, but if we can arouse the laity without politics by continually reiterating these facts before the people, we shall feel that our labors have not been in vain.

Dr. A. E. Baldwin, Chicago—I think a great deal of harm comes from posting notices. I know they would agree with me in many large cities. Here is a case of a child that has scarlet fever. That child was isolated from the household, and no one allowed to see it except the trained nurse; no one else ever went near it. Would it be right to isolate that whole building by putting a placard on the front door? They would not be incautious; they could not be affected at all by being in another part of the house. Does that little card, eight by fourteen, offer any protection? Not at all. It does nothing of the kind. I agree with Dr. Latham that there should be a rigid enforcement of separation between those affected and those who are not affected, children as well as adults.

Speaking of what Dr. Brown has said, I do not think tuberculosis is dangerous to us as long as it is in Dr. Brown's mouth. It is not spread in that way. The only circulation it has is in the air or in food and drink, and the remedy he suggests would do no good in lung difficulties. If we could have any preparation to take into the mouth to destroy tubercle bacilli it would have no effect one-half hour later. I think there is such a thing as carrying this matter too far. Notwithstanding the isolation of these cases, we will find these Krebs-Loeffler bacilli in many mouths that are healthy, and we can not look into every mouth. That is impossible. When we admit that they may be found in the mouths of people who are perfectly healthy, we can readily see that isolation cuts no figure. I do not want anybody to misunderstand me; I do not want to throw open the door to every diphtheric case, but there are a great many things that we advocate that are really not as far-reaching as we think they are. They are not as effective as we think they are. I do not think that anyone who knows me can say that I have ever been an advocate of any chance or careless method in any way, shape or manner, but I do think we had better be a little cautious and know what we claim before we make any great claims for our belief. It is far from proven that many diseases that are called contagious or infectious are really so.

Dr. G. V. I. Brown—In the isolation hospital in Milwaukee, during an epidemic of scarlet fever, the patients were immediately placed upon a system of treatment which included the disinfection of the mouth with hydrogen dioxid and oxygen. The result was that out of one hundred cases there was not a single one affected by any of the various sequelæ that follow that disease. The suppurative process which very frequently is likely to follow that disease, and that almost invariably affects the middle ear, was entirely absent, and there is no question about the value and efficacy of that treatment, and it is now becoming an established factor in the treatment of other diseases. The same is largely true of typhoid fever and some modifications of that disease.

Dr. Alice Steeves, closing the discussion—This paper has been the outcome of my own observation and experience. I have reason to believe that there has been infection from improperly cleansed instruments in several cases of which I had the care, and I thought it would be well to bring this matter up. In speaking of sterilization and cleanliness, I feel that especially in the schools ordinary cleanliness is not properly demonstrated to the students. We must have ordinary cleanliness before we can have surgical cleanliness.

THE TREATMENT OF CUTANEOUS CANCER.*

M. L. HEIDINGSFELD, M.D.

CINCINNATI, OHIO.

The treatment of cutaneous cancer has been one of the most serious and difficult problems with which the profession has had to deal. The remedies, which at one time have been highly extolled, at another, severely condemned, are exceedingly varied in nature and innumerable in number. Two remedies which are received with much favor to-day, zinc chlorid and white arsenic, have been extensively used, the one for scores of years, the other for centuries. The use of these two remedies, in the hands of certain specialists, was attended, at least in selected cases, by eminently successful results; in others there was absolute failure, if not death of the patient.

Caustics were much in vogue in the treatment of cancer, until the recent advances in surgery were made possible by the introduction of antisepsis and anesthesia. Since then the knife has been freely employed, and its use was gladly welcomed, with the hope that free and radical extirpation would assure a positive and permanent cure for a condition whose erstwhile therapy was exceedingly painful and of more or less doubtful value. It is needless to add that our fondest hopes have not been realized, and after a rich experience covering a goodly number of years, the most sanguine must admit that the results have not been gratifying.

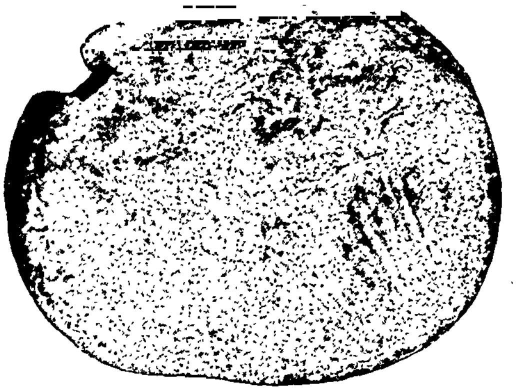

Fig. 1.—J. W. M. Photograph of piece of tissue removed from posterior border of scalp, measuring 3½x2½x½ inches, by means of pastes, applied by a cancer-quack. Sub-epidermal surface, which is traversed by some muscular bands, removed from the underlying muscular tissues.

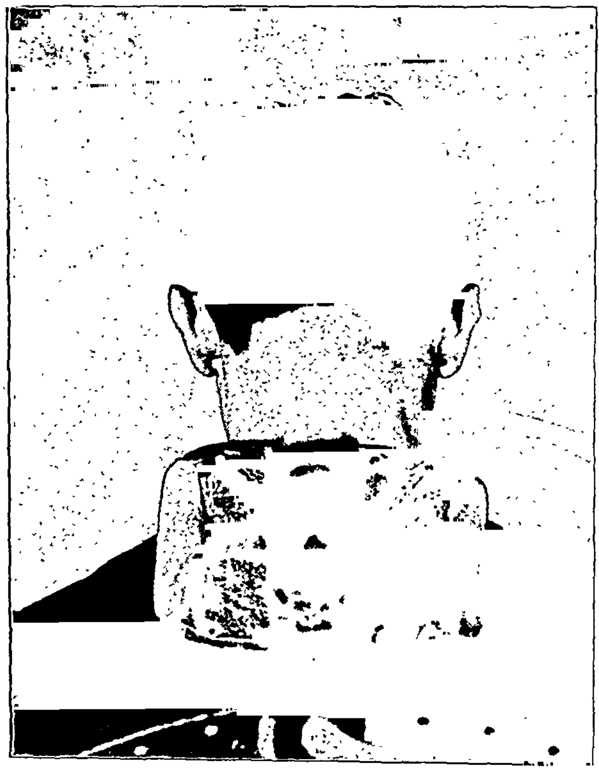

Fig. 2.—J. W. M. Cicatricial deformity resulting from the removal of tissue (see Fig. 1), by means of the cancer-quack's paste.

Coley[1] states that "however ardent advocates we may be of surgical intervention, to the exclusion of all other methods in the treatment of cancer, we are nevertheless confronted with the fact, that at least 75 per cent. of all cases are, or at some time become beyond the reach of the surgeon's knife." William Watson Cheyne,[2] surgeon of King's Hospital, London, speaking of cutaneous cancer, states, "that the very removal of the local disease, may, in some cases, rid the patient of the disease altogether. The favorable results are best seen in cases of epithelioma affecting the extremities, after amputation. R. Volkmann gives the cures, that is, the *patients well three years after operation*, as 51 per cent." Allowing for 15 to 20 per cent. recurrences after this period, we can readily see that the knife promises only about 30 per cent. of cures, and then, for the most part, at the cost of amputation of the affected extremity.

---

* Read in the Section on Cutaneous Medicine and Surgery, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

[1] Wm. B. Coley: The Practitioner, 1899.

[2] William Watson Cheyne: Ibid.

Both the profession and the laity have gradually learned to realize those facts, and the nonchalance of the former and the skepticism of the latter have been instrumental in removing these individuals from our observation, to the care of the so-called cancer-quacks. As a direct result the number of these quacks have steadily increased, and in every large community there are not a few who have attained a considerable degree of local eminence, with the reputation of having effected a long line of, not failures and recurrences, but successful and permanent cures. A great deal of this reputation, I may dare say, is not undeserved; in place of dejecting the patient with the utter hopelessness of his disease, the danger and uncertainty of a severe operation, or the loss of an extremity, the quack encourages him *with hopeful assurances and promises*—pledges that are not always plighted.

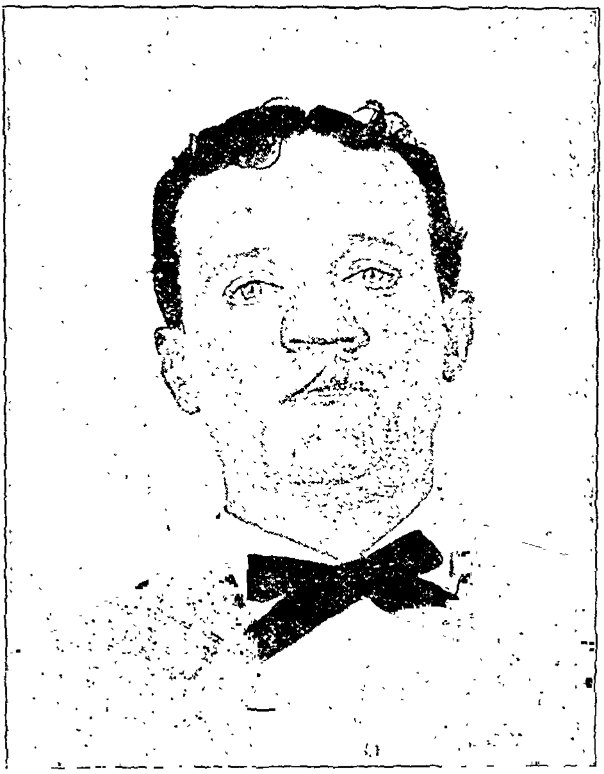

Fig. 3.—J. W. M. Cicatricial deformity of lip, resulting from the application of a cancer-quack's paste.

The agents these so-called cancer-quacks employ, are, for the most part, caustics, preparations of arsenic, zinc, potash, lime, and the common acids. An interesting specimen was recently removed by one of our local surgeons from the posterior border of the scalp. The alcoholic specimen measures three and a half by two and a half inches in its two diameters, and one-half inch in thickness, and has been removed with the subcutaneous tissue, fat, and even with some of the muscular fibers of the underlying tissues; allowing at least a third for shrinkage after hardening in alcohol, the fresh specimen must have measured almost five by four by three-quarter inches. It had been removed in a round, clean-cut manner, by the application of a brownish-red paste, and separated spontaneously, with considerable pain and reactionary inflammation, after an interval of four or five days. The disfigurement from the resulting cicatrix is considerable. Microscopic examination of the removed area reveals the tissues to be in an excellent state of preservation, the

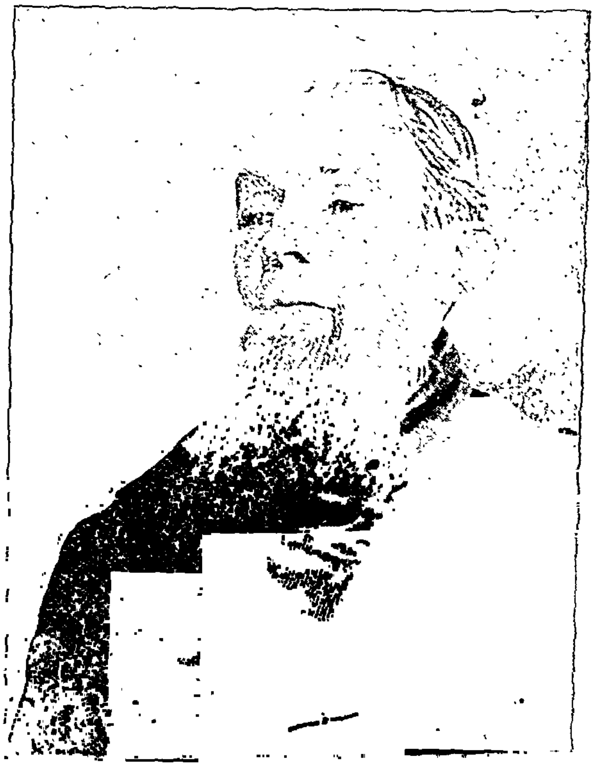

Fig. 5.—W. K., March 21, 1901; epitheliomatous ulcer of 2½ years' duration completely healed 29 days after institution of treatment.

pidermis, sweat and sebaceous glands, hair follicles, nd blood-vessels being histologically well preserved. he blood-vessels are extensively thrombosed and at the order where separation from the surrounding tissues as occurred there is very extensive inflammatory infilration. The specimen was removed from an individual 7 years of age, and the only indication for its removal as a papular, pigmental syphilid. A second area cancerous?) was removed from the upper lip, and the ncer-quack was engaged in removing a third from the side of his throat, when the patient, perforce from ain and distress, withdrew himself from his treatment. This cancer-quack enjoys a lucrative practice and an extensive local reputation, and no one can doubt that a remedy of this character can prove thoroughly efficacious in a case of genuine cancer.

Time does not suffice to permit me to take up all the remedies which are extensively used and extolled to a greater or less degree by various members of the profession. I wish to conclude with a brief narration of my results with a remedy which at present is receiving general and favorable recognition. I refer to arsenious acid, mixed with equal parts of pulverized gum-arabic, to which sufficient water is added to make a paste of the consistency of butter, and enough cocain crystals to alleviate the anticipated painful reaction, as recommended by Marsden, Robinson, Gottheil, and Stelwagon. I have found it expedient to add 10 per cent. glycerin before adding water, which prevents the paste from becoming too dry and therefore prolongs and intensifies its action; the reactionary pain is also diminished by the glycerin.

M. Ft. paste. Sig.: Apply locally.

The paste is applied directly to the ulcerated surface, after being uniformly spread on a piece of muslin or linen, which has previously been carefully adapted to the affected area. It dries in the course of five to ten minutes, and remains firmly adherent until its removal 12, 24 or 36 hours later is indicated by the pain, intensity of the reaction or the degree of the treatment required. The after-treatment consists in the application of simple, soothing, antiphlogistic remedies, in the form of indifferent pastes, Wilson ointment, combined with cold compresses saturated with the solution of alum acetate. The resulting pain is usually slight, often scarcely sufficient to disturb sleep. There is some reactionary inflammation, in the form of redness and swelling, which is usually limited to the ulcer and its immediate neighborhood.

I have not found it essential to prepare the surface by the application of caustic potash, in stick or solution, green soap, etc., as recommended by numerous authors, in order to cut down the epidermis and to remove scales, crusts, and keratoses, which can interfere by their presence with the action of the arsenic. In one case I felt obliged to remove a crust by means of a compress of oil, applied for twenty-four hours. The application of caustic potash, even though momentarily applied, is exceedingly painful, and its irritating and destructive action being directed against healthy and diseased tissue alike, it is considerable of a gain to be able to dispense with its use.

In most instances one application of the arsenic has been all that was necesary; in several instances I felt obliged to repeat the application for fear the resulting reaction was not sufficiently intense. In one of these cases the ulcer was surrounded by an elevated wall of tissue, epitheliomatous in character, which did not share the reaction; the second application, made twelve days later, remained as ineffectual as the first, and though the wall remained, cicatrization was complete in twenty-nine days. During the following two or three weeks the wall also underwent spontaneous involution and has entirely disappeared.

From this I infer that arsenic possesses not only an elective action, exerting its chief influence on the weaker and less stable pathological tissue, sparing the more resistant surrounding normal tissue, but also exerts a specific influence over the cancerous tissue whereby it inhibits its growth and prevents its further spread and development without entailing its direct destruction.

My experience is too recent to permit me to judge of the permanency of the results; its immediate effects are certainly all that can be desired, and if nothing but this crowns our efforts it should hold a very high place as a palliative measure.

I regret that time does not permit me to compare its action with other remedies that have been recommended from time to time, and are in extensive use to-day, namely, formalin[3] (Ravogli), acid nitrate of mercury, pyrogallic acid, zinc chlorid, electrolysis, (Corlett), injections of alcohol, Vienna paste, mixed toxins of erysipelas and bacillus prodigiosus.

As far as my experience permits me to judge, I am strongly impressed that this method of treatment possesses decided advantages over the former methods. It is prompt in results, easily limited and controlled, spares the healthy tissues, exerts a marked specific influence, and produces relatively little distress and subjective disturbance. It promotes prompt cicatrization, and speedily converts a freely discharging, foul-smelling ulcer, filled with soft mushy granulations and flabby detritis, into a firm, clean-looking sore; inhibits the discharge and materially diminishes the inflammation of the surrounding tissues. The peculiar influence it exerts over the diseased tissue, without entailing its actual destruction, leads to the belief that the best results are to follow its application in mild rather than in severe forms; in other words, under-treatment rather than over-treatment is indicated. Time must prove whether or not the results are temporary or permanent in nature, but even in its present form it should prove to be an invaluable agent, if only palliative in nature.

DISCUSSION.

Dr. W. T. Corlett, Cleveland—Although I have not had much experience with the treatment Dr. Heidingsfeld advocates, I have had quite an extensive experience in the treatment of superficial epithelioma. During a period of about twenty years, after a wide range of remedial measures, I have of late years selected electrolysis almost exclusively in the treatment of epitheliomata. I believe it presents many advantages over other methods and even that advocated by Dr. Heidingsfeld. I can further say for electrolysis that it is extremely satisfactory, and while I do not advocate any exclusive method, believing the special requirements of the case should always be considered, yet, as I have observed the results attained by surgeons, the results are to me quite convincing that the methods resorted to by dermatologists are, as a rule, more lasting than when the knife is exclusively used. The method of employing electrolysis is extremely simple; anybody can do it with patience and a little skill. I often use an ordinary McIntosh battery of eighteen cells, which is sufficient to supply electricity for an ordinary operation, lasting twenty minutes to an hour. The patient must first be anesthetized, and when the lesion is small, he may be discharged as soon as he comes out of the anesthetic. Very little, if any, after-treatment is necessary. Of a large number of cases, some of which had existed many years, the diagnosis having been confirmed by microscopic examination, in only one instance, so far as I have been able to ascertain, has the growth returned. In this case the disease had developed beyond the point when any operation holds out much hope.

Dr. William Allen Pusey, Chicago—I have followed the method Dr. Heidingsfeld suggests, using Marsden's paste and frequently using the zinc lotion recommended by Unna, with most excellent results. I am surprised at the rather pessimistic prognosis Dr. Heidingsfeld gives, for it is a fact that cutaneous carcinomas are the most benign we have and we should expect a good result in all cases not complicated by metastasis. I had occasion to look through my records about a year ago and found that during the first three and a half years of practice that I treated eleven cases of epithelioma, either by curettage or by the application of paste without curettage. In all these cases, except one, there was a microscopic diagnosis. Each one of these cases I have been able to follow and there has been no recurrence. I do not think that is an unusual result with this method; I think Dr. Heidingsfeld exaggerates the importance of these lesions, if they are treated early.

I have lately treated an epithelioma by a new method, to which I would call attention in this connection; I have made use of x-rays. This case has been in existence twenty years. It is a superficial form of carcinoma involving only the skin. It has been treated by the best surgeons in Chicago and they had left a large epithelioma on the shoulder. This was put under treatment by exposure to x-rays, in January of this year. I exhibited the case last week and I do not believe anybody was able to detect any suspicious tissue remaining, the shoulder is apparently entirely healed, although, of course, further time is necessary to confirm the cure.

Dr. L. E. Schmidt, Chicago—I have had considerable experience in the x-ray treatment of cancer of the skin and up to the present time have not seen any favorable results, although I have practically followed the method used by Dr. Pusey, and originally laid out by Dr. Freund of Vienna. I do not see exactly why the dermatologist should lay the scalpel aside altogether. Without doubt there are a considerable number of cases that can be treated more successfully in a surgical way. Take those cases that border on the mucous membrane, both of the anal and oral, and other regions. In these positions the various pastes that are recommended can not be used with ease or safety.

Dr. Joseph Zeisler, Chicago—We have been using various medicinal agents in the destruction of cancer for a long time, but I have noticed during the last two years the enthusiasm with which these so-called quack methods have been taken up by dermatologists of good reputation. In my entire practice I have never made use of such agents, and knowing their constitution I believe I shall never use them because the method seems to me so thoroughly unsurgical, and after all, the treatment of epithelioma should be surgical, understanding by that term the thorough removal of everything that is diseased. It seems to me more rational to do this operation in the cleanest, most rapid manner possible. It seems more reasonable to do it in this way than by the slow course of cauterization, where we can not always limit the operation. I do not desire to be understood as wishing to relegate the treatment of epithelioma to the surgeon, for I believe the dermatologist will always find a field for this work. I am happy to say that some excellent surgeons in Chicago have referred cases of epithelioma to me. When I speak of the dermatologist removing a cancer in a surgical way, I mean by the use of the curette, scraping down to healthy tissue. It is surely possible to remove a superficial epithelioma in this manner. When it has ceased to be a superficial epithelioma I leave it to the surgeon. When it is complicated with deep-seated glandular troubles I do not touch it, because I do not claim to be a surgeon. After thorough curetting it is also proper to have a thorough cauterization, and I have always found the nitrate of silver in substance the best thing to use. There are others in this room who can testify to the excellent results I have had in such cases. In one case an epithelioma of the lip was removed in this way and healed in eight days in the most beautiful manner. As long as we have this clean method of removal with modern methods of local anesthesia, I will stick to it until I learn of something better.

---

[3] Ravogli: Jour. A. M. A., 1899.

I want to express the hope, not based on experience but on observation, that in treatment by the x-ray we may perhaps find a valuable resource in this department of medicine. That the x-ray is an excellent means of destruction in lupus we have opportunity to observe in Chicago, where Dr. Pusey has used the method extensively. I believe it is as yet too early to form a definite opinion about it, but I am in hopes that the x-ray will prove to produce excellent results.

DR. BURNSIDE FOSTER, St. Paul—In the treatment of malignant dermatoses where, as is often the case, it is quite impossible without a microscopic examination to discriminate absolutely between cancer, lupus or rodent ulcer, I have had great satisfaction, after having removed everything possible by mechanical means, in the use of superheated air after the Holland method. I hope to show you to-morrow a very beautiful result in the treatment of a case of lupus after this method. So far as the treatment of skin cancers is concerned, it seems to me quite impossible to lay down definite rules which will apply to all cases and it seems rather a waste of words to attempt to do so. Undoubtedly, some cases are best treated by excision and some cases are best treated by erasion followed by the application of some caustic. Where it is quite evident that, by either of these methods, the growth can be entirely removed, we must be guided by the probable cosmetic result. I have had considerable experience in the destruction of skin cancer with caustics and I shall never be persuaded that the knife could have accomplished such beautiful cosmetic results as I have seen by these methods.

DR. D. W. MONTGOMERY, San Francisco—In the treatment of epithelioma you simply have to destroy it, with the curette, chromic acid, nitrate of silver, arsenic, or with the knife, but you must destroy it. The great advantage the physician has is in knowing a large number of methods of slow destruction. The arsenical method is undoubtedly a good one, but in looking over the literature I was impressed with the variation in strength of these arsenical preparations; it is wonderful how various these strengths are. Marsden himself never used a paste weaker than 50 per cent.; nor stronger than 75 per cent. To my mind 50 per cent. seems to be the least that one can use in order to get a good cautery. There are a number of cases where you can not use arsenic, and there are quite a number of other cauteries you can not use. For instance, a man was sent to me with an epithelioma on the back of his hand at the base of the finger that had developed on a scar. I could not use arsenical paste on that for fear of eating into the tendon sheath. I did not want to use a curette for the same reason; in fact, I did not want to use anything on it but the knife, so I sent him to a surgeon and it was so removed, and I think it was taken out thoroughly. I would not for a moment think of discarding the knife, and I would not think of discarding the actual cautery. French authors prefer the actual cautery. When a chemical is indicated I think the one they use most frequently in Paris is caustic potash. It is an admirable caustic. I remember the case of an old lady from whom I could not have removed a cancer of the nose with anything else. She was very nervous and would not stand the sight of any instrument, and she would not stand the injection of cocain, but in the course of a sitting I ploughed the growth with a caustic potash stick. I suppose it caused her a good deal of pain, but pain does not trouble these people. Having become accustomed to the application of arsenic I do not think I shall ever entirely give up its use.

DR. DAVID LIEBERTHAL, Chicago—Every method of removing cutaneous cancer without a cutting operation is valuable, and especially so if it does not cause much pain. We should not forget that there are patients who would not submit to an operation. That hot air, concerning the efficacy of which Dr. Foster spoke, might give good results; I can readily understand, considering the coagulative properties of heat, which will most readily affect diseased tissue. The first cases treated by x-rays were reported by Drs. W. Johnson and W. H. Merrill in the *Philadelphia Medical Journal*, December, 1899; and at the International Congress of Paris, 1900. Dr. S. Steenbeck reported two cases, one of which developed upon the base of a lupus vulgaris. These cases, which were all of limited size, resulted in cure. In a case of epithelioma which I reported May 25, 1901, in THE JOURNAL of the American Medical Association, and which was the size of the palm of the hand, the x-ray was applied for a period of three months by Dr. Haiselden. At first there was noticed a decrease in the secretion and some flattening of the tumor, but in the further course the tumor increased and surgical interference was resorted to. This case did not extend beyond the fascia. It is my opinion, considering all these cases, that the x-ray should be tried in all cases of epitheliomas of small size, but in those of larger size other methods will have to be employed.

DR. C. W. ALLEN, New York City—The treatment of cancer in this way was originally advised by reputable physicians and it was only because quacks took it up, it seems, that we dropped it. Now, after these many years, we have for some reason taken it up and I think it has gone far enough in this renaissance to prove to us that the method is excellent and not to be dropped again, especially the use of arsenic. Electrolysis I have also used, but rarely as the sole method of treatment. I often use it in connection with other treatment to destroy outlying suspicious changes from the normal vascular dilatations, little outgrowths at a distance. Occasionally I have used it as the only method, with great success. Just before starting from home I saw a man in whom three years ago I removed an epithelioma from beneath the eye, using nothing but the needle, and he had as soft a scar as one could wish for.

I failed to gather from Dr. Zeisler's remarks that he differs from the rest of us. I think most of us are inclined to curette before paste is applied, especially if there is no base that can be acted upon quickly by the arsenic. We all have our preference as to caustic, most of us using arsenic, some caustic potash and others nitrate of silver. Patients come to us as dermatologists because they refuse to be subjected to the knife and they will nurse their cancer and will die with it, if necessary, or let it go on to the destruction of an eye, or whatever organ it may be, rather than to have it operated upon with the knife. If they come to us and we offer them nothing but the knife there is nothing for them to do but to go to the quack. I think we should bear that in mind and offer something they will accept. You can curette without letting them know you are doing a surgical operation. I never say to a patient: "I am going to curette you and it will cause bleeding." I simply curette them and then apply caustic, or whatever I am going to use. I do not confine myself to any one method; I wish to speak of a combination method I have carried out. That is, after applying arsenical paste, which I mix with orthoform instead of acacia, and put in crystals of cocain, I put on arsenic solution, namely, arsenic, alcohol and water. I make daily applications of this and if I have missed any cancerous tissue the arsenic continues to attack it. The wound heals quickly and there are no cicatrices.

Just before leaving New York I saw a man who had had epithelioma of the penis. Dr. Leusgarten had examined the tissue and pronounced it epithelioma, and it seemed to me clinically unmistakable. I had applied the Bogard paste, which contains besides arsenic, zinc chlorid. That was eleven years ago and the man has remained perfectly well since. I do not advocate the use of arsenic in epithelioma of the penis, unless you get the case early. I have recently used this method in six or eight cases of epithelioma of the lip. Three were rather remarkable as to age, being 23, 26 and 28 years old. I have seen these men subsequently and they appeared to be cured, with a soft cicatrix. If we can do this with superficial epithelioma of the lip we can do it in epithelioma of the penis; the tissues of the penis resist invasion and it is a long time before the glands are enlarged.

In regard to epithelioma on the back of the hand, I think caustic is applicable there and I have used it in epithelioma of the palm, with a perfect result. One case was a recurrence; it was the mother superior of a convent, and the cancer returning I used caustic paste. The palm healed beautifully and I do not think it has returned. Arsenic is not apt to go into the tendons; it does not have a tendency to attack healthy issue. With zinc chlorid there is danger of the healthy as well as the diseased tissue being attacked. I think if we combine several treatments, using, if necessary, two or three in some cases, we will do better than the surgeon can do. That is my impression after using these methods twenty years.

Dr. A. W. Brayton, Indianapolis—Where so many speak we learn many things, and some that are not true. Nothing is so amusing as the talk about the benign tendency of arsenic by which it avoids normal tissues and selects the epithelial growths. That does not appeal to me; I do not think it has pathological or clinical support. I will say, however, that in the case of xeroderma pigmentosum I have had under observation for eight years, and that of her sister who has been under my observation since birth with the same disease, the inhibitory tendency of arsenic has been very satisfactory. After the tumors are raked out with a sharp finger-nail or spoon the application of a mild solution, even Fowler's solution, seems to inhibit their further growth.

The statement made this afternoon that impressed me most is that the old people who have cancerous growths to be removed bear the pain well, but they are victims of terror; they dread the knife and they dread the actual cautery. I do not think we err in removing cancer of the lower lip by grasping the lip between the thumb and finger, cocainizing it, scraping it with a sharp spoon, and then using the actual cautery or acid nitrate of mercury. I frequently use the Paquelin cautery in such cases.

I agree with Dr. Zeisler that we should work in a cleanly way, but I think the application of such caustics as we can control in our office, the removal of the epithelioma with a spoon, followed by the application of carbolic acid to deaden the nerve, then the acid nitrate of mercury, is a cleanly and efficient treatment. I give them half an ounce or so of acetanilid to apply to the wound from time to time and find it sufficient. Orthoform combined with arsenic may have a beneficial action, but I doubt its anesthetic action under such conditions.

Dr. M. L. Heidingsfeld, in closing the discussion—In regard to the prognosis being rather pessimistic, it is not my own; because my experience has been entirely too limited to permit me to express myself on a subject of that character. The opinions I have given from the literature are those of Coley and Cohen, and one or two other men. I have investigated very carefully, and nearly all the men I had occasion to look up have given a guarded prognosis in epithelioma or cutaneous cancer.

In spite of the statement of Dr. Brayton and others this afternoon, I am firmly of the opinion that arsenic does possess an elective, specific action in cancer. I have had several cases, all over 65 years of age and some as old as 84, all typical looking epitheliomas, some having the characteristic wall, slightly turned out, infiltrated and hard. Anyone who has done extensive pathologic work knows that the border in particular shows the characteristic pathologic condition. I was fearful of my results, that these ulcers would not heal; the walls have disappeared. I can only account for that by supposing that the arsenical paste has an elective action, because it does not destroy the tissue but inhibits its growth. This feature makes it a more desirable drug than anything else we have. All other processes that destroy the tissue act on the normal tissue as well as the pathologic tissue. In these cases the treatment is very satisfactory, the ulcer needs to be undertreated rather than over-treated.

As to whether the knife is more applicable than a method of this kind, that will have to be demonstrated by results. It does not matter very much whether it is the knife or the application of a drug, as long as we get results. If we have an agent which clears up these ulcers in a comparatively short time, and I have had them clear up completely in four to six weeks, that is certainly as well as any result we could obtain by surgical intervention.

As to whether arsenic can be applied on the back of the hand, I take it that it can be applied anywhere, with the same result. If the treatment is not carried out extensively there is no reason why it could not be applied to these areas as well as to others.

RELATION OF SYPHILIS TO BLASTOMYCETIC DERMATITIS.*

HENRY G. ANTHONY, M.D.
Professor of Skin and Venereal Diseases, Chicago Policlinic.
CHICAGO.

Since the discovery of actinomycosis hominis by Israel, in 1878, it has been shown with the aid of microscopic preparations preserved in the laboratories of Europe, that cases of this disease were previously observed and reported as cases of sarcomata; cases of mycetoma have been proven to be caused by actinomycosis; the disease has been found in the brain; it has been observed under the clinical diagnosis, appendicitis; Neisser has reported a case which he at first diagnosed as a papulo-pustular syphilid, but which on further examination proved to be actinomycosis cutis, and, lastly, branching forms of the bacillus tuberculosis have been found in the lungs which Hektoen[1] tells us can not be distinguished from actinomycosis pulmonalis.

Ever since observing the case which my colleague, Dr. Herzog, and I reported last year as a case of blastomycetic dermatitis engrafted on syphilitic ulcers,[2] I have entertained the opinion that should it become established that blastomycetic dermatitis is a distinct disease, it was destined to have a somewhat similar history.

The first cases were discovered hidden away under the diagnosis tuberculosis verrucosa cutis. My case showed that a search should be made among the fungous syphilids, and it suggested other possibilities of diagnosis. The object of our present communication is to explain our views in greater detail, and to answer the many objections which have been raised to my opinion that there was a syphilitic basis to this case.

It will be recalled that the patient stated that for sixteen years ulcers, which he described as simple ulcers, were continually appearing and disappearing on the anterior surface of the leg; these ulcers left scars, some of which were quite deep, others superficial, having a semi-circular and stellate arrangement (symptom of Fournier), and that at the end of sixteen years those of these ulcers which were in a state of activity suddenly took on a changed appearance; they became covered with little warts, and, starting from these lesions, this wart-like eruption spread upward over the thigh, so that at the end of four years the entire thigh was one enormous plaque, covered with wart-like papillæ, the upper border of which was limited by a deep, firm infiltration, and seven months before the patient came under our observation, frambesiform lesions, which produced a very offensive discharge, developed on the foot. The patient never entirely recovered.

In treating of the vegetating or papillomatous and frambesiform syphilids, Kaposi[3] says: "It is a fact that vegetating formations frequently develop on specific nodules. They are not in themselves specific, inasmuch as they correspond, histologically, to those which develop on a simple inflammatory base, and, like these, originate from an exuberation of granulations or hypertrophy of papillæ, the same as in condylomata lata, the base alone being syphilitic. They can only be recognized as syphilitic by the characteristic infiltration or ulceration of the border."

If this statement is correct, the most rational explanation of these vegetations which sprout on a syphilitic base is that they are due to a secondary infection. The micro-organisms which are present in these growths have not been sufficiently studied, but the striking resemblance of some of the cases to blastomycetic dermatitis and their clinical history certainly suggest the possibility of this disease being discovered among these fungating syphilids.

---

* Read in the Section on Cutaneous Medicine and Surgery, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

Like blastomycetic dermatitis, these syphilids are rare; they are papillomatous fungating plaques; lasting for years; involving enormous areas of cutaneous surface; sometimes steadily progressing during their entire course, and sometimes remaining in a quiescent stage for a long time, to suddenly take on great activity of development. They are exceedingly rebellious to treatment; at times finally disappearing under the administration of potassium iodid, only to reappear at some future time, and at other times only partly disappearing under treatment.

Were they due to ordinary pyococci they would be common, and we would not expect them to last so long and to steadily extend in spite of antiseptic treatment.

When potassium iodid is administered in cases of blastomycetic dermatitis, a peculiar reaction may sometimes be observed in the plaques; an inflammatory exudate is thrown out around and upon the lesions which, when the lesions are superficial and small, resembles very closely the reaction which occurs in lupus vulgaris after an injection of Koch's lymph. Where the lesions are deeper and their base is markedly infiltrated, the infiltration increases and the plaque increases in size, and sometimes ulceration of the plaque occurs. This reaction is usually accompanied by iodism. These changes have been observed in syphilis.

The objection has been raised to my assigning a syphilitic base to my case that the histo-pathology was distinctly the histo-pathology of blastomycetic dermatitis and not the histo-pathology of syphilis.

We have never said that the histo-pathology of this case was the histo-pathology of syphilis. What we have said, and what we now wish to emphasize, is that this was a case of syphilis cutanea vegetans of Kaposi. We took it for granted, and we had a right to, that every dermatologist would know that there was something special regarding the histo-pathology of syphilis cutanea vegetans of Kaposi.

Thirty years ago Kaposi[4] said that there was something special regarding the histology of these vegetating syphilids, inasmuch as they resemble common warts on microscopical examination. To-day Unna[5] says: "Under certain conditions the epithelium growth which develops on tuberous syphilids may, without atrophy of the epithelium, undergo a peculiar change, which causes it to resemble certain cancers, especially the rodent ulcer." In some cases, then, these eruptions resemble the rodent ulcer; in other cases, the common wart.

Blastomycetic dermatitis, when viewed with one-fourth power lens, so closely resembles the rodent ulcer that if a section be given to a competent pathologist, but one who is not on his guard for blastomycetic dermatitis, he will, as I can assert from personal experience, almost invariably report that it is a section from a rodent ulcer. In my case a few sections showed the wart structure, as described by Kaposi.

The findings with the oil-emersion are to be left out of consideration in this discussion, because the syphilids have not been sufficiently studied with the oil-emersion.

In criticism of our diagnosis, it has been pointed out that there was no history of syphilis in the case. We do not feel called upon on this occasion to enter into an extensive consideration of that cardinal principle of diagnosis, which has no place in scientific discussion outside of under-graduate instruction; namely, that a negative history of syphilis counts for nothing in the diagnosis of tertiary lesions; as a matter of daily clinical experience, cases may be seen in any dermatological clinic which may be diagnosed as syphilitic almost to a certainty without there being any history of previous syphilitic disease.

Of far greater importance, to my mind, is the objection that in each and every case of blastomycetic dermatitis which has been reported to date there is a negative history of syphilis. A negative history of syphilis counts for nothing in the diagnosis of an individual case, but if it can be shown that there is an entire class of cases in which the history is negative, it is a matter of the utmost importance. A review of the cases reported since the original article of Riehl and Paltauf, in 1886, to date, in which the differential diagnosis rests between cutaneous tuberculosis other than lupus and syphilis, and which were diagnosed syphilis, shows that there are but few in which there was a clear history of syphilis, and, furthermore, we will point out the fact that there are not many of these cases in which there were present lesions or lesion relics, such as might be produced by syphilis, but are not known to be produced by blastomycetic dermatitis or tuberculosis verrucosa cutis, such as perforation of the palate, *le nez a lorgnette,* periosteal nodes, etc.

These facts are capable of several interpretations. The next point for discussion is whether the clinical picture presented by this case was the clinical picture of tuberculosis verrucosa cutis or syphilis cutanea vegetans. This involves a discussion of the differential diagnosis of these diseases. That they are to be differentiated may be easily established. Riehl and Paltauf[6] say that not every plaque, the surface of which is covered by wart-like papillæ, is to be diagnosed their dermatosis, but only those cases in which all the symptoms taken together present the clinical picture which they describe. Brugger[7] says that syphilis sometimes so closely resembles tuberculosis verrucosa cutis that a differential diagnosis can only be made by the administration of potassium iodid.

Nearly all German writers agree that one of the chief points in the differential diagnosis of these diseases is that the outer zone in tuberculosis verrucosa cutis is a lilac-ring, as Besnier calls it, which almost entirely disappears on pressure, while in syphilis the outer zone is a distinct, firm infiltration, such as was present on the upper border of our case. Where there are a number of lesions present they do not all present the indurated border, and clinical experience has taught me that the induration may be entirely absent, and still the case be syphilitic, a point not mentioned by German writers, although we find in German literature reports of cases in which induration was not present, of which the following, reported by Ostermayer,[8] of Buda Pest, is an example: "The patient, a woman, aged 31 years, presents a lesion on the chin and cheek which is the size of the palm of the hand, and has been present a few months. On examination, the lesion is seen to be a plaque of a pale-red color, with a warty, papillomatous, uneven surface. The plaque rises abruptly from the surrounding healthy skin, just as the surface of a lawn rises above a surrounding walk. It is of oblong form, and ulcerated only in two pea-sized places. The papillæ are 8 to 10 mm. high, and 2 to 3 mm. wide. The surrounding skin is normal, and the plaque is as if set into normal skin. When first seen the case was diagnosed 'lupus papillaris,' but when no lupus nodules were found on the periphery of the lesion, the patient was stripped, and ulcerating gummata and periosteal nodes of the tibia were found, which were sufficient for the diagnosis, even in spite of a negative history." This is one of the few cases of this kind in which lesions were present which, so far as is now known, are not produced by blastomycetic dermatitis, but are produced by syphilis, and were this patient to present herself in any dermatological clinic of this country to-day, the lesions would be immediately examined for the presence of blastomyces.

The next point is the size of the plaque. Most authorities agree with Jackson,[9] that a fully developed patch is the size of a silver dollar.

Besnier and Doyen[10] speak of very large plaques, which they state are always fissured; their writings convey no idea as to how large these plaques may become, so that the only means at our command of forming an idea of the size which the plaques may attain is a review of the cases which have been reported, and nowhere can we find a case co-extensive in size with that of the entire thigh.

All authorities agree that tuberculosis verrucosa cutis is a disease which develops very slowly. Joseph[11] says that it takes fifteen to twenty years to form a full-sized plaque; others say from three to fifteen years. In one of Fabry's[12] cases, the disease involved one-third of the back of the hand in two years' time, which is rapid development. We can find no case where a plaque the size of the entire thigh formed in four years, as was observed in our case.

The following case, entitled "A Papillomatous and Ulcerating Lesion of the Forearm of a Doubtful Nature," reported by Brocq,[13] illustrates the importance this authority attaches to rapidity of development as a point in the diagnosis of verrucous tuberculosis:

"The patient is 59 years old, apparently healthy. For the past eight months he has had a lesion of the left forearm, regarding the nature of which I would be pleased to have the advice of my colleagues. At the present time it consists of a plaque, slightly oval in form, the long axis of which is from 5 to 6 centimeters in length, situated near the median line, and slightly internal to the anterior surface of the forearm. It presents an outer zone of redness, which is slightly violaceous, disappearing partly on pressure. The tissues of this zone are a little infiltrated, and the infiltration increases towards the center, and decreases towards the periphery, without any sudden demarkation from the healthy skin, but the limits of the lesion are sufficiently marked by the color. The skin in this zone is smooth and devoid of apparent superficial lesion. Inside of this zone there is a median portion much more irregular where the integument is mammillated, cut with deep fissures, as if torn open, and pseudo-papillomatous. One might say that the skin has been excavated by numerous small ulcerations, the borders of which are granulating. The tissues in this part of the plaque are soft, but deeply infiltrated. On pressure a purulent serum exudes from divers openings, but in small quantities. The physiognomy of the entire patch is not that of a gumma, either tubercular or syphilitic, but, on the contrary, more that of tuberculosis verrucosa cutis of Riehl and Paltauf. *It is not painful* either spontaneously or on pressure. It developed rapidly in two months; it then became papillomatous, markedly indurated, and formed a decided projection. It appears that the patient has had several lesions resembling furuncles, which he scratched, and this lesion is a transformation of one of these furuncles. The only two diagnoses which appear probable to us are, 1, a variety of tuberculosis approaching, as we shall see, verrucous tuberculosis of Riehl and Paltauf, but the development has been *so very rapid,* and, 2, an inoculation of some parasite, which has produced a lesion resembling the Briska button. This last diagnosis is impossible, because the patient has always lived in France, and also because it has not exactly the appearance of the Briska button."

In closing the discussion, Brocq remarked that it resembled most of all tuberculosis verrucosa cutis. Were this case to present itself in any dermatological clinic of this country to-day, there can be no question but that the first diagnosis which would be considered would be blastomycetic dermatitis.

In addition to the importance which Brocq attaches to the rapidity of development, it should be noted that the case impresses the observer as being a secondary infection. The induration present in this case is also to be borne in mind.

The frambesiform lesions of the foot developed in seven months' time. There was no disease of the subjacent bone, as is usual in large plaques of tubercular vegetations, and the secretion from these plaques was of the very offensive nature mentioned by Kaposi as one of the symptoms of syphilis cutanea vegetans.

From these findings it will be seen that a syphilitic base was assigned in this case, on the following evidence:

1. That for sixteen years ulcers were appearing and disappearing on the anterior surface of the leg, leaving scars which resembled syphilitic scars; at the end of sixteen years the ulcers then present took on a changed appearance; they became covered with little warts, which spread rapidly.
2. The infiltrated border.
3. The size of the patch and rapidity of development.
4. The histo-pathology.
5. The character of the frambesiform lesions.
6. The result of treatment.

These symptoms are certainly sufficient to exclude tuberculosis verrucosa cutis, and with that disease excluded, one of two propositions is correct: either ours is a case *sui generis,* the like of which has never before been observed in the history of medicine, or else such cases have been previously observed, but have been reported under some other head than that of tuberculosis verrucosa cutis. Inasmuch as the opposition has not claimed that such cases have been heretofore reported under any other head, than those mentioned, we are justified in concluding that such cases are either *sui generis,* or syphilis cutanea vegetans, and that point we have sufficiently argued.

The question will immediately occur to your mind: Do the above-named symptoms absolutely establish a syphilitic base to the case in question, in view of our present knowledge of blastomycetic dermatitis?

It must be acknowledged that if blastomycetic dermatitis be recognized as a distinct disease, these symptoms are totally insufficient, but inasmuch as they are the symptoms on which our diagnosis has always depended, they must stand until blastomycetic dermatitis is fully recognized as a disease. Zeisler[14] says: "*The* question is whether we have a right to overthrow well-defined, sharp and precise clinical pictures which we have always recognized, on account of the occasional occurrence of these organisms." All German authorities who have expressed an opinion on the question of blastomycetic dermatitis have taken a most conservative stand.

Jadassohn[15] simply says: "Potassium iodid, which usually acts quickly in late syphilis, can influence actinomycosis, and, as has been recently stated in one case, it can exert an influence on blastomycosis, but it has no influence on tuberculosis."

In his recent text-book, Jarisch[16] says: "The proof that blastomyces are the cause of skin diseases must be left to further investigation, as well as their importance in the etiology of tumors."

Kromayer[17] is most emphatic in his statement. He says: "Buschka's case is especially characterized by the fact that cultures inoculated into the skin of the patient himself produced cutaneous ulcers like the original. In this respect this case differs from any case reported to date, not excepting the case reported by a triumvirate (Hyde, Hektoen and Bevan), which resembled tuberculosis verrucosa cutis. In this case yeast fungi were found, which were assigned as the cause of the disease. They did not produce fermentation of sugar, and they only produced slight symptoms of disease in animals. In this case, as well as in all other cases, it is advisable to place an emphatic query after blastomyces as a cause of disease. To date the Buschka case is the only case of blastomyces in the human race."

Pelagatti[18] has obtained a *pure culture of blastomyces from a case of lupus.*

Ricketts[19] has isolated three varieties of blastomyces from seven of Professor Hyde's cases.

In discussions before the Chicago Medical Society it has been stated that these eruptions contain not three, but seven, different varieties of blastomyces. I can not conceive of a disease being due to seven different varieties of a given micro-organism. There are a great many varieties of actinomycoses, some of which are saprophytic, and the same must be true of these micro-organisms.

A study of the history of the fungating syphilids shows that in the past from time to time first one disease and then another has been excluded from this classification. Kaposi has participated in this work of sorting out diseases from among these vegetating syphilids, and it is very possible that the time has now arrived when we will be able to separate one more disease, which has heretofore been concealed among these eruptions. There are several facts which might be mentioned which support this contention, but there are a good many which indicate that such is not the case. It is a matter of doubt. There is very little evidence in support of the contention that blastomyces is the cause of the disease.

Before any conclusion can be arrived at, a thorough study of blastomyces occurring in cases of surgical tuberculosis must be made.

DISCUSSION.

Dr. J. Nevins Hyde, Chicago—I am already on record on this question and have nothing to add to what has been already set forth in print. I would like to ask Dr. Montgomery to say something about an interesting case, of which he has full records, and which we regard as the missing link between the cutaneous forms of blastomycosis and those in which there has been visceral involvement, as in the well-known record made by Busse and Buschke of their patient.

Dr. F. H. Montgomery, Chicago—There are two or three interesting points in regard to this particular case, which has been under observation for a number of years. There was a diagnosis of syphilis or carcinoma and tuberculosis, the case being passed upon by competent pathologists. I showed it to at least a dozen excellent pathologists in this country and Europe, and each one said it was not tuberculosis, it was not syphilis, it was not carcinoma. The nearest they could come to it was that it was syphilis and tuberculosis. The case was considered unique. I will not go into details, the primary records, which were lost, have been recovered and the slides are in our possession showing infection of the lungs with blastomyces. The clinical history pointed to systemic infection and the man died of infection resembling recurrent attacks of pneumonia. In the other cases, twenty-five or fifty of them, having a distinct clinical type of cutaneous lesion, differing as a whole from all other known dermatoses, blastomyces have been found in the tissue, in many of them a dozen or more have been discovered. From these organisms animals have been inoculated and lesions produced in internal, deep-seated organs, blastomyces recovered and again cultures produced and cutaneous lesions developed. We are not able to produce these typical lesions in man. We can not take lesions from a typical verrucous cutis and produce them on the skin. Regarding the statement of authorities previous to any knowledge of blastomycosis, these men knew tuberculosis, they know syphilis and they recognized cases that did not belong to either category; they tried to assign them to some known disease.

Dr. Joseph Zeisler, Chicago—Inasmuch as Dr. Anthony has honored me by expressing an opinion I gave some time ago, I feel that it is my duty to place myself on record by stating that I am rapidly coming to the opinion held by Dr. Hyde, Dr. Montgomery and others who look upon this group of cases so far observed as belonging to a distinct entity and probably due to a peculiar organism. My change of mind is largely due to clinical observations made possible by the presentation of a series of cases by Drs. Hyde and Montgomery which seem to me remarkable. As long as we could judge these cases only by pictures I had doubts, but I have recently had occasion to see the difference of observing a disease on the living subject and I am almost prepared to say that the next case of blastomycosis that comes to me I will not wait to judge from the clinical lesion. I believe all of us who can look back over an experience of twenty years in dermatology, if we could go over our cases, would find one here and there that baffled us; sometimes there was a diagnosis of vegetable syphilid, sometimes of a peculiar tuberculosis of the skin, sometimes a new formation, and so on. I think Dr. Hyde and Dr. Montgomery deserve a great deal of credit for placing the clinical picture of this disease in such shape that we shall soon be able to recognize it without the aid of the microscope. They have demonstrated in all their cases the same micro-organisms, which are not found elsewhere, and the value of their discoveries should be recognized.

Dr. A. W. Brayton, Indianapolis—I do not recall anything more interesting in dermatologic discussions than the report of the Dermatological Association at the meeting in Washington, unless it be the frank statement of Dr. Zeisler in regard to his present attitude on this subject. Of course, on the outside we recognize that there have been two camps in Chicago regarding blastomycosis and its relations to syphilis and tuberculosis. It has been my fortune to meet three cases, which occurred in our city, of which I have made some notes embodied in a paper I shall present to the Section. I am familiar with the opinions of gentlemen living in localities where this disease has not occurred, Drs. Bowen and White of Boston and the group of New York dermatologists, in whose practice it has not been met. I had in mind with that group Dr. Zeisler until his very frank admission this afternoon that he, like Dr. Johnson, of New York, may have entertained for a time erroneous opinions in regard to the etiology of that very definite clinical condition that goes by the name of blastomycosis of the skin, blastomycetic dermatitis—the name given by Gilchrist and which out of courtesy to his work will go down in history as the proper name for this disease. I am glad that Dr. Johnson, after having conversed with Dr. Welch, of Johns Hopkins, and gotten his views in regard to the etiologic relationship of the yeast plants that are found in the lesions, modified his conclusions, as Dr. Zeisler has done this afternoon.

I was struck with Dr. Zeisler's statement, and have included the same views in the notes I have prepared for presentation, that if he were to see in his dermatologic practice now a disease presenting certain features he would promptly regard it as blastomycosis upon the clinical presentation alone. I have only seen three cases. I saw Dr. Hessler's case, and am reminded that these yeasts differ under different cultures. The yeast in Hessler's case, Plimmer's yeast, and the yeast in the case I diagnosed on April 10, and discharged as cured just before coming here, differed. I regard it as a very simple thing to diagnose in the two cases I have met and studied clinically, and the accounts I have read of other cases coming directly under the care of gentlemen in Chicago, agree with my own; it is quite possible, I think, when you see a case in your office to conclude that it is blastomycosis. You take it in connection with the clinical progress; rule out syphilis; rule out tuberculosis; rule out cancer and you have an entirely different clinical picture. Take the last case I had, a woman of 23, who eighteen or twenty months ago had a slight abscess on the finger, which spread in spite of various treatments until it involved nearly the entire surface of the little finger and part of the ulnar surface of the right hand. The inflammation, the irregularity, the excessive pain, a boring, constant pain at night, which were present in these two cases I think of great value in the diagnosis. It is a matter of considerable interest that these cases should have developed to such a great extent in Chicago, and the dermatologic profession is fortunate, I think, in having men there who took it up with the insistence and persistence they have shown. It is good that they were divided into two camps for study and research, bringing out the full details of these cases; such papers as Dr. Anthony's are highly stimulative. But I am surprised that so many pathologists, going over their material for a long time back, did not find the yeast plant in the tissues. I presume there are good reasons for it; most likely its absence. We have no explanation at hand for its prevalence in Chicago. There are certainly localities where yeasts are abundant.

Dr. R. R. Campbell, Chicago—Dr. Anthony's paper recalls a case we met with at the Policlinic about five years ago, which, with our knowledge at that time, we diagnosed as syphilis, but the microscopic findings presented something peculiar, the nature of which was never determined. The patient was placed on iodid of potassium and in three days returned with marked iodidism, claiming that he had caught cold, the eruption presenting an inflammatory reaction which the patient described as erysipelas. He was kept on the iodid for some time and in about six weeks the eruption entirely disappeared. Up to the present time no further manifestation of the eruption has been noted. That these cases, with those of actinomycosis and syphilis, disappear under the iodid is rather unfortunate as no stress in the diagnosis can be laid on the fact of their disappearing under the iodid. To my mind there is no question but some cases of syphilis very decidedly resemble blastomycosis as described by Dr. Hyde, and as shown in some cases I saw through the courtesy of Dr. Hyde at the Chicago Dermatological Association. I do not think, however, that Dr. Hyde claims, as Gilchrist says he does, that it can be clinically and positively diagnosed at the present time.

As to the disease occurring more frequently in Chicago than in other places, I do not think there is any peculiarity about that. The disease was taken up there and investigated by Drs. Hyde, Montgomery and Ricketts, and it simply shows more industry on the part of Chicagoans than others.

Dr. Maximilian Herzog, Chicago—It appears highly probable that the condition which has been called blastomycetic dermatitis is a disease *sui generis*. I do not feel competent to decide from a clinical standpoint whether this disease is to be always looked upon as a primary condition or whether it may be engrafted upon syphilis or tuberculosis. It is certain that the disease under discussion presents a characteristic histopathology. We find the following: An extensive proliferation of epithelial structures. The epithelial cells in proliferating form pegs which penetrate deeply into the derma and the subcutaneous connective tissue. We do not, however, find, as we do in carcinoma, a tendency to form well-defined alveolar nests. In the proliferated epithelial structures we find small miliary abscesses, the abscess cavity being filled with ordinary polynuclear leucocytes, eosinophilic cells and plasma cells. It is right here in these abscesses where we find the double-contoured micro-organisms which have been called blastomycetes. Drs. Hyde and Montgomery and their associates certainly ought to be complimented on the great enthusiasm with which they have taken up the subject of blastomycetic dermatitis and upon the extensive results they have obtained. I have had an opportunity to examine a number of pure cultures and micoscopic preparations derived from their cases and presented at one of the last meetings of the Chicago Pathological Society. From the statements then made by Dr. Ricketts, who did most of the microscopic work in connection with the cases of Drs. Hyde and Montgomery, and from my own observation then made on their material, it appears to me that from their cases were obtained three kinds of micro-organisms: 1. A type which does not form any spores and which therefore would have to be classed with torula or oidium. 2. A type which forms spores and which ought therefore to be classified as a true saccharomyces. 3. A micro-organism which forms a mycelium which divides dichotomously and which forms spore-bearing hyphen. The latter micro-organism approaches in type such higher moulds as aspergillus and verticillium.

I believe Dr. Montgomery is mistaken when he says that Dr. Ricketts succeeded in changing one of these forms into another by merely transplanting on different culture media. To the best of my knowledge Dr. Ricketts never succeeded, for instance, in changing a non-sporulating form into a sporulating form, or vice versa. In view of these facts it appears to me that the etiological relation between these different types of micro-organisms and blastomycetic dermatitis is not yet fully established, because it seems somewhat strange that micro-organisms so different in type should produce an absolutely identical histologic picture. The case of actinomycosis which has been cited is not fully identical with the present case because the different forms of actinomycosis do not vary as much as the different forms of micro-organisms found in the skin disease, now generally called in our country blastomycetic dermatitis, do vary. We must consider the possibility that the micro-organisms found are present only in a symbiotic relation in our disease and that the true cause of what we call blastomycetic dermatitis may be still hidden away from us. You know that yeast-like micro-organisms have been found by San Felice in sarcoma, yet we can not consider that their etiological relation to sarcoma is fully established. The same, it appears to me, is true of blastomycetic dermatitis. Yet, be this as it may, I can only repeat what I said before, that Dr. Hyde and his associates deserve all possible credit for the work which they have done in connection with the disease under discussion.

Dr. F. H. Montgomery, Chicago—Dr. Ricketts did not intend to make a positive statement classifying these under three different heads. He has not demonstrated to his entire satisfaction spores in any one organism. There are highly refractive buds, but none have been found distinctly in the capsule. The spores have not been cultivated. The truth is that investigators are not yet ready to give us a definite classification of these organisms. Another fact along the same line is that investigators have demonstrated a number of distinct species which are pathogenic, so it is not necessary to limit the origin to one species of blastomyces. As to the posibility of it being a bone tuberculosis or bone syphilis, of course we can not say. We are accumulating evidence and are trying to present it but are not drawing absolute conclusions as yet. With a series of cases of these very severe, extensive lesions lasting from two or three to ten or twelve years, where there is no history and no other evidence of syphilis; it is certainly a strong argument against syphilis.

Dr. **Henry G. Anthony** (closing the discussion)—At the recent meeting of the American Dermatological Association I had the pleasure of listening to a paper on blastomycosis by the president of the Association, Dr. Shepherd, of Montreal. He showed lantern slides of cases of very peculiar granulomata which had passed under his observation in times past, and which he stated he would examine for blastomyces, were they to come under his observation to-day. His remarks recalled to my mind figure 216, page 733, of Taylor's work on "Venereal Diseases," edition of 1895, which is cut of a papillomatous syphilid such as we have under consideration; consequently I showed this cut to Dr. Shepherd and asked him if he would examine such a case for blastomyces; he said he would and that the fact that blastomycosis is influenced by potassium iodid convinced him that cases of this disease had been heretofore reported as cases of syphilis. I refer to this matter with the Doctor's permission.

I hope that I have not given the impression that I have not a full appreciation of the work done by Professors Hyde and Montgomery. I do not think there is anyone who appreciates any more fully the value of their work than I do. Dr. Montgomery states that he has not drawn any positive conclusion in regard to this disease; neither have I. I distinctly stated that I had not drawn a positive conclusion and that I hesitated as to whether we might look upon the disease as a distinct entity.

In regard to Dr. Hyde's remark about Dr. Bowen, I wish to say that I had no intention of quoting Dr. Bowen in regard to the relation of blastomycosis and syphilis. I thought that the way I worded it was clear. He referred to the subject in general; he meant he was not absolutely convinced that blastomyces caused the disease.

In regard to the distinct clinical type, I think I can pick out a case of blastomycosis as well as almost anyone; but at the same time I feel that the cases which can be picked out are in the minority; that there are just as many, even more cases, in which no man can say beforehand that the blastomyces are present in the given case. I have seen such cases and that is why I have not laid such stress on these distinct clinical features as others do. Furthermore, I showed a case at the meeting of the American Dermatological Association which everyone who saw the case, acknowledged did not present the characteristic appearance regarding which so much has been said.

In regard to the importance of the case Dr. Hyde referred to in his first remarks, the reason why I did not lay as much stress on that as he did, was because of the fact that the blastomyces were discovered in it, and the importance of the case was worked out and realized so long after the observation of the case that it seemed to me to throw it into doubt.

The statement made before the Chicago Medical Society, that these eruptions contain seven different varieties of blastomyces has not been published; hence, it may be disputed; but there can be no disputing Dr. Rickett's statement, that he found three different varieties of blastomyces in Dr. Hyde's cases, because he has published an account of his findings in the *Illinois Medical Journal*, reference to which I have appended to my paper. He says: "From seven cases the organisms have been cultivated. They fall into three groups: 1. The yeast-like, resembling those of Hektoen, Hessler, Busse and Curtis. 2. The oidium-like. 3. The mould-fungus type, resembling the organism isolated by Ophüls and Moffit from the protozoic (?) disease." Study shows that all these have common generic properties, and are separated only by specific characteristics which are more or less variable. In accordance with pre-existing nomenclature, they all belong to the genus oidium. "Blastomyces" is considered not sufficiently inclusive.

A CASE OF ERYTHRODERMA SQUAMOSUM.

A. RAVOGLI, M.D.
CINCINNATI, OHIO.

A group of mild affections of the skin of a transitory nature, characterized by a desquamation of the epidermis, was called pityriasis by Bateman. Biett gave a more definite meaning to pityriasis, which he considered a mild chronic inflammatory process of the most superficial layers of the derma, accompanied with continuous exfoliation of small epidermic scales. Devergie gave an interesting description of pityriasis, which he called rubra, and we can say that he established a new pathological entity. Pityriasis rubra (Devergie), however, has nothing to do with another disease of squamous nature, which was after a while described by F. and H. Hebra under the name of pityriasis rubra. F. Hebra[1] said that the name pityriasis rubra could be given to any disease of the skin which during its whole course was not accompanied by any other symptoms but a constant, intense, brownish-red discoloration, without marked infiltration, without formation of papules, fissures, vesicles or discharging, with some itching sensations, seldom localized, but usually spread over the whole surface of the body. He referred to only 14 cases to his knowledge, showing it to be a rare disease, having usually a fatal termination. The patients are extremely sensitive to cold, complaining of continuous chills. The disease progresses without any interval, the skin is deeply red and is covered with thin scales. Gradually the skin becomes thin and shiny, showing a certain degree of sclerosis; the hair becomes dry and brittle, and falls off; the nails easily break, the whole process seems to be that of an inflammation of the chorion and of the epidermis, terminating in atrophy of the skin. The syndromic picture of the disease shows a very severe affection, while it is possible that cases of the same pityriasis may exist limited to some part of the body and of benignant nature. Vidal and Brocq have referred to cases of pityriasis of different degrees of intensity, from a very mild to those of a pernicious nature. In the dermatological practice the observation of eruptions consisting of red patches covered with thin epidermic scales not rarely occurs, and these eruptions are not accompanied by severe symptoms of malaise nor by deep affections of the general system. James C. White[2] referred to a case of this kind, which he called by the name of the author, Brocq's *erythrodermie pityriasique en placques disséminées.*

The name of *erythrodermies exfoliantes* was first applied to these eruptions by Besnier to characterize a group of affections the symptoms of which are a red surface (*erythros,* red) and a continuous desquamation. In his classic notes to the lessons of Kaposi this group of squamous affections of the skin is headed by the name *erythrodermies exfoliantes lentes ou chronique idiopathiques primitives.* These he divides into four varieties. One is a form of a chronic dermatitis with different ways of starting, which after a long chronic stay ends in a condition of the skin somewhat like that of the pityriasis rubra. Another type is a kind of dermatitis of a tardy and chronic course, accompanied with a leukemic condition, enlarged lymphatic glands, and also to the pre-mycotic stage, which although confused with eczematous forms, are yet neatly separated. A third variety consists of a kind of dermatitis spread on the whole surface of the skin, red, with fine scaly epidermis, connected with latent infections, chronic suppurations, etc. The fourth variety, as sketched by Besnier, would be a kind of pityriasic condition of the skin, which remains as the result of pityriasis rubra follicularis.

It will be interesting now to refer to the history of the case, a boy, F. B., 3 years old, well developed, well nourished, with blond hair, white skin, blue iris. He is the youngest of seven children from healthy parents. The parents say that all their children have had the same affection in a milder degree between the ages of 4 and 8, relapsing in character, lasting from several weeks to several months. The little patient is already suffering for the third time from an attack of this kind, the first being when 2 years old, the second on Jan. 18, 1901, for which he was in the hospital four or five days, and the third relapse is the present, entering the Hospital on March 5. The patient has never suffered in general health; pulse and temperature have always been normal; he has never had sore throat or any other complaint. The skin of the entire body, with the exception of the palms of the hands and soles of the feet, is red and covered with scales, varying in size and appearance according to the different anatomical regions. Although the eruption is so universal, yet when the scales have been removed the red surface showed that they were made up of round patches of considerable size and by their confluence appeared the *uniform redness*. The redness disappeared somewhat when pressed under the finger, to return immediately. No papillary or follicular projection could be seen on the whole red surface, nor were the furrows of the epidermis altered. No subjective symptoms were present, the little patient never scratched, never complained of any pain. The redness was of a light rose-red hue, which was somewhat deeper in color when exposed to the cold air. The whole surface was covered with thin white scales of different appearance according to the different anatomical regions. On the forehead the scales were somewhat thicker and mixed with the cutaneous *smegma* and remained adherent with a tendency to form a whitish layer. (Fig. 1.) The hair is abundant, brown in color, in normal condition, but the scalp is covered with thick scales which, as in the forehead, have a tendency to accumulate. The neck was also covered with scales which were very thin in the anterior part and thicker and more abundant in the posterior. (Fig. 2.) The whole body was covered with scales covering red surfaces of the skin; they were much thicker and more abundant on the sides of the chest and abdomen, while the anterior surface of the neck, the sternal region, the middle of the abdomen, pubis and genito-crural regions were entirely free. (Fig. 3.) The shoulders and the back were just covered with scales, and in the same way the arms and the legs showed that they were deeply affected by the eruption. The hands had a few scales around the wrists, the phalanges were free from eruption and the palms and soles were perfectly normal. The nails did not show any alteration. The skin appeared rather rough, but taking it in folds did not show to the touch marked infiltration. Two applications of cod-liver oil on the body were sufficient in order to have all the scales detached, leaving the surface of the skin in the form of round red spots disseminated over the body. In these spots no papules or no follicular projections could be found, showing that the affection consist of a superficial process of the superficial layers of the derma and of the epidermis. That the disease is not the result of a permanent alteration of the general system is shown by the short period of the attacks, and by the easy yielding of the same to treatment. Furthermore, at the beginning and during the attack no fever, no itching, no stomach or bowel complaint ever caused any sufferings of the patient. The urine has been found constantly of a normal acid reaction and specific gravity, and normal in qualitative contents. The blood examination was made with the following result: red corpuscles, 5,400,000; white corpuscles, 8400; small lymphocytes, 23 per cent.; large lymphocytes, 2.1 per cent.; polynuclear, 73 per cent.; eosinophile, 1.4 per cent, showing that the blood is in normal condition. In different bullous affections we have found the eosinophile bodies increased to 19 per cent., and in one case of dermatitis herpetiformis (Duhring) at the time of an attack the eosinophiles reached 43 per cent.

The bowels were perfectly normal, the boy enjoyed a good appetite and perfect digestion. He never complained of any discomfort, was of a rather quiet and peaceful disposition. He slept soundly, never woke up at night, showing the mildness of the affection, which had not much influence on the general system.

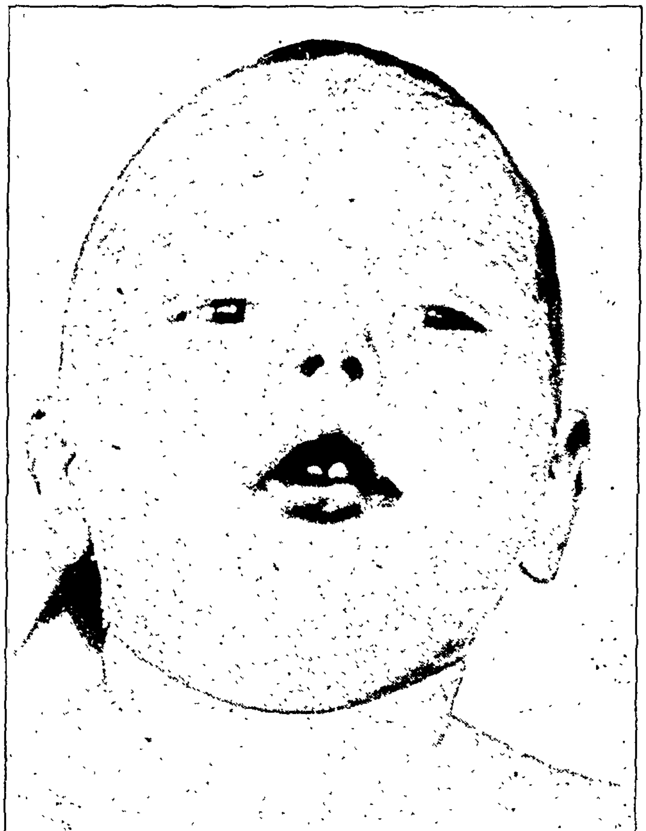

Figure 1.

This peculiar affection, which had already relapsed three times in the little patient, had nothing to do with any of the common diseases of the skin. It was not an eczema, nor an eczema seborrhoicum, it was not psoriasis nor a pityriasis rosea. Although somewhat like ichthyosis, yet it had nothing to do with that disease, which is a permanent skin affection. The erythema scarlatiniforme was soon eliminated, knowing that it is a disease with a cyclic evolution, accompanied with fever and inflammatory symptoms of the skin and mucous membranes. There remained for my case only one nosological place, which is between pityriasis simplex and pityriasis rubra (Devergie), a disease which has for its principal symptoms redness of the skin and exfoliation of the epidermis, a disease mild and relapsing in character, causing no general reaction and no subjective symptoms. It is therefore an affection which finds its place among the *erythrodermies exfoliantes lentes ou chroniques idiopathiques primitives*, as established by Besnier, with some affinity to the affection called by Brocq,[3] and accepted by James C. White as *erythrodermies pityriasique en plaques disséminées.* I said some affinity with the case of Brocq, for the reason that he described the disease as made up of spots varying in size from 2 to 6 centimeters, while in my case the spots were larger and more confluent so as to form an equal surface. The age of the patient must surely have had a great influence upon the appearance of the disease, when we think that the patient of Brocq was a woman of 45, the patient of White a man of 38, and my patient a child of only 3 years, and it was only the third time the affection has made its appearance.

Pathology.—A piece of skin was removed from the deltoid region, and was treated in formalin 2 per cent., hardened in alcohol and the sections stained with hematoxilin (van Giesen), and polychrome methylene-blue by my assistant, Dr. M. L. Heidingsfeld.

In the specimens as it appears from the accompanying illustrations, Figs. 3 and 4, the horny layer is thicker and ragged with epidermic shreds, but the stratum spinosum and granulosum have a normal appearance. The stratum lucidum is fairly preserved, while it was lacking in the case of White. Although microscopically no papules and no alterations of the furrows of the skin were present, yet in some places the papillæ are somewhat enlarged, forming a kind of flat papillary elevation consisting of four or six papillæ. The blood vessels are greatly enlarged and can be seen in the papillæ and in the chorium. An infiltration of small cells is especially remarkable in the connective tissues of the papillæ and in the subpapillary layer. These infiltrating cells are found always more abundant around the blood vessels, which show a great increase in their perithelium. The glands and the hair follicles are enlarged and their epithelium is somewhat increased.

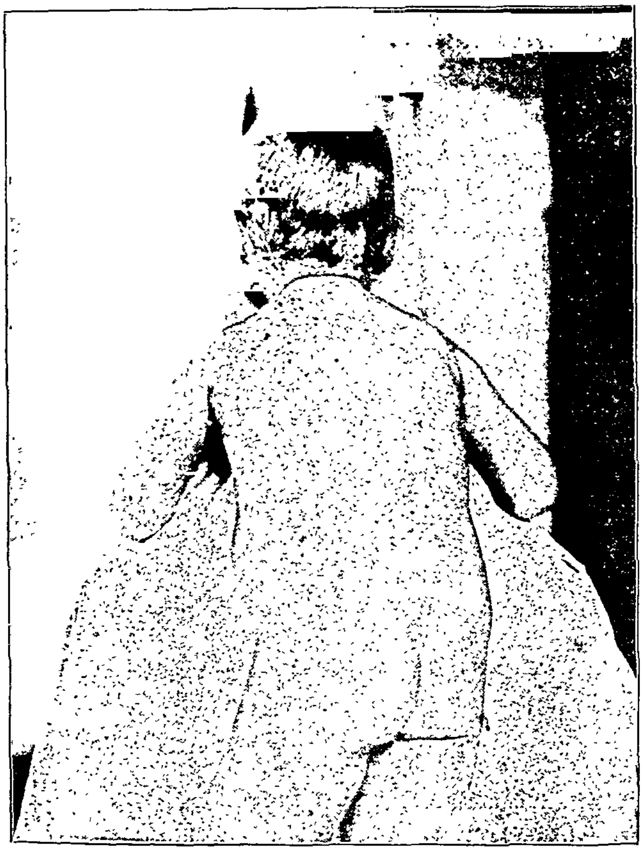

Figure 2.

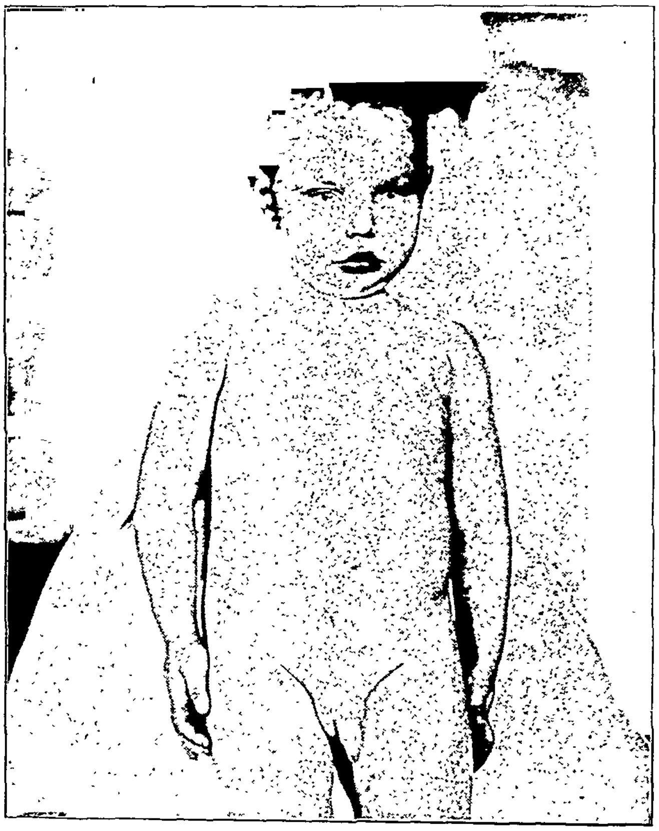

Figure 3.

The entire pathological feature of the erythroderma consists in the enlargement of the blood vessels and in a perivascular cellular infiltration, which produces alteration of the nutrition at the epidermis and as a result the hardening and the exfoliation of the horny layer. These are signs of a well-marked inflammatory process revealed by the increase of the cells of the connective tissue of the papillary layer and around the blood vessels of the subpapillary layer. These cells are different from those which are found in the subepithelial layer in cases of lichen.

In erythroderma the patches of the skin are red, rough and scaly. Unna[4] points out two important characters which differentiate erythroderma from pityriasis rubra (Hebra) and pityriasis rubra seborrhoica, which consist in a mild cellular infiltration of the papillary layer and the marked adherence of the epidermic scales. Pityriasis rubra pilaris and ichthyosis are to be referred to hyperkeratoses, while erythroderma is only a parakeratosis spread to large surfaces of the body. In pityriasis rubra pilaris the enlargement of the pores of the skin is pronounced in form of papules of different size and elevation, while in erythroderma no apparent papules are to be seen nor enlargement of the furrows, but only a red flat surface covered with brown-like scaliness.

I do not find that our case has much similarity to the erythrodermie in the sense of v. Düring,[5] who describes it as presenting a general diffused redness and infiltration of the skin, which is developed in lichen neuroticus from the follicular papules and from interfollicular erythema, which disappears leaving a deep browning pigmentation. In our case no apparent papules nor enlargement of the pores can be seen, but pathologically we have found an increase of the papillæ with enlargement of the blood vessels and accompanying infiltration of small round cells in the papillary and subpapillary layer and a desquamation of the horny layer.

Differential Diagnosis.—Indeed, a physician who has not much practice with squamous affections of the skin, finding himself in the presence of a case like this subject of our study, where the surface of the body is all red and covered with scales, would find some difficulty in establishing a nosological place for the disease. As stated above, this affection has no relation to the pityriasis rubra of Hebra, which from the beginning to the end is revealed by an intense redness of the skin with a thin desquamation of the epidermis. The redness is universal, the disease progresses constantly without intermission. The skin gets thinner, brilliant and retracted, ending in a sclerotic atrophy. In erythroderma the redness which appears equally diffused, consists of groups of eruption in red round patches, which have appeared clearly after removing the scales by means of annointing the skin with cod-liver oil. This clinical characteristic is perfectly in accordance with the pathological alterations where we have found places where groups of papillæ were somewhat enlarged and somewhat above the level of the others, as shown by our illustrations.

The difference between the two affections is therefore neatly marked by clinical and pathological characters. Erythema scarlatiniform, so well described by Besnier, and pointed out first by Ferreol under the name of desquamation scarlatiniforme recidivante, is an acute affection, accompanied with fever, general malaise, sore throat, with an eruption of red patches, itching and burning, which after four or five days begins to desquamate. This nosological type is entirely different from our erythroderma squamosum, where the scaliness on a red surface forms the principal characteristic of the disease, where no acute invasion, no subjective symptoms, no fever have ever appeared.

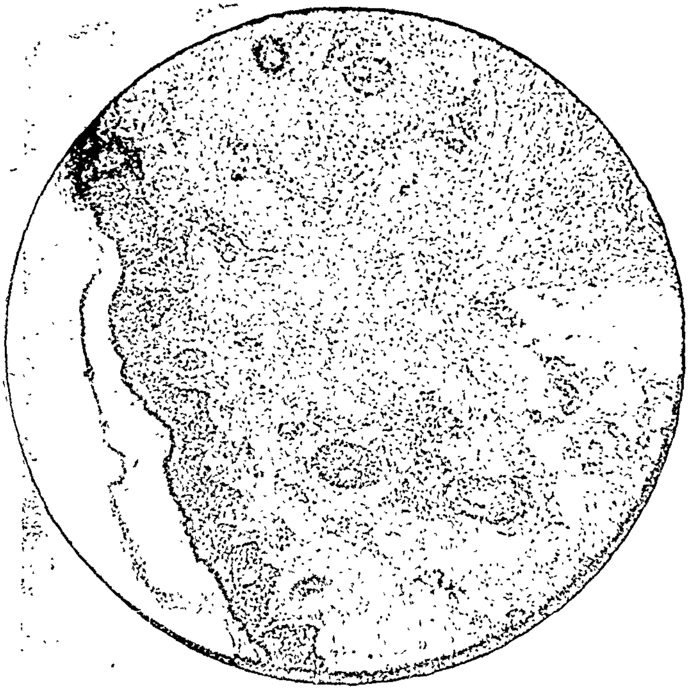

Figure 4.

Etiology.—The pathogenic causes of the erythroderma in general are extremely obscure and difficult to be established. In our case we can not find any apparent cause which externally may affect the skin directly, but we must rather admit a cause probably of a toxic origin formed in the system, *which affecting* the center of the *vasomotor* nerves is capable of producing hyperemia of the chorium with exudation and consequent alteration of the nutrition of the epidermis as revealed by the scaliness. From the statement of the parents that their other children between the ages of 4 and 8 years have suffered attacks somewhat similar to those affecting our little patient, we could infer that there must be some autotoxic condition in the whole family of an hereditary nature which is capable of producing those attacks. All that we can say is to resort to the explanation so well given by Tommasoli of the autochthonous poisonings which are formed within the system. In fact, an alteration of the physio-chemical condition of the fluids of the organism may easily happen. Ptomains are easily formed on account of retained toxic elements, which in some cases may favor the multiplication of microbes, and in other cases may produce disturbances of nervous and vasomotor nature, *which make their appearance* on the skin.

Treatment.—In regard to the treatment, the affection has easily yielded to our method, which has consisted in removing the scales by annointing the whole body with cod-liver oil and then wrapping the patient in a coarse woolen blanket. After two days the skin was perfectly free from the presence of the scales. Then an application of vaselin with resorcin and salicylic acid according to the following formula, has brought the skin to a normal condition.

℞: Resorcin	ʒss	2	65
Acid. salicyl	gr. x		
Vaselin fl.	℥i	32	

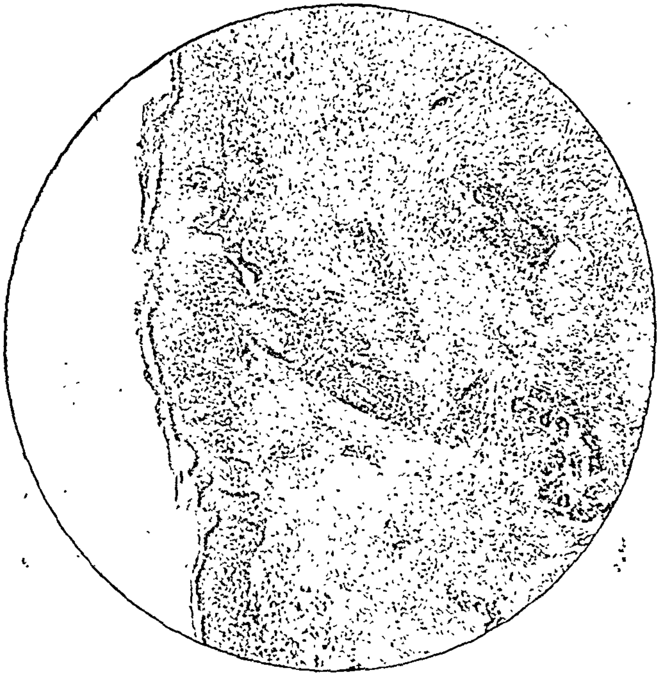

Figure 5.

Internally we have given a solution of potassium arsenitis (Fowler), from three to six drops three times a day.

From the results of the treatment it is clear that the affection is of a benignant nature, which does not produce severe symptoms, but it has the tendency to relapse, *showing that the cause producing* the affection has its seat in the system from autotoxic origin.

The Physician at Watering Places.—At the recent German Congress of Balneology, Liebreich *observed that it is the* physician, more than the chemical factors, that make the success of a mineral spring resort. He ascribed to this fact the fine results attained in the German watering-places, *which lead the world, he asserted.*

Clinical Report.

HIP-JOINT AMPUTATION BY MEANS OF THE WYETH PINS.

EARL M. GILLIAM, M.D.,
COLUMBUS, OHIO.

The issue of May 19, 1901, of THE JOURNAL contains an interesting article by Professor Wyeth on "Bloodless Amputations at the Hip-Joint." The writer having had recently a case desires to report it as follows: C. H., aged 8, residing at Corning, Ohio, fell from a tree, a distance of 20 feet, sustaining a compound fracture of the upper third of the left femur. Oct. 27, 1900, three weeks after the accident, he was brought to St. Anthony's Hospital in a septic condition. Pulse was 140; temperature 104. The limb was much swollen and filled with pus. An incision was made on the outer aspect of the thigh and considerable pus liberated. The muscular structure was found to be disorganized, the bone comminuted, and the medullary canal filled with purulent matter. The bone was devoid of periosteum for more than five inches, and no evidence of bony union found.

His condition demanded immediate operation and it was decided to amputate at the hip-joint by the Wyeth method. After thorough preparation, the patient was brought to the operating-room the following morning and chloroform administered. Fifteen minutes previous to the giving of the anesthetic, morphia one-fourth grain and atropia one one-hundredth grain, were hypodermically injected. The limb was deprived of as much blood as possible by elevation, no bandage being used for fear of driving septic material into the circulation. Two long mattress pins were then introduced, and Esmarch's tourniquet applied. No trouble was experienced during the operation until disarticulation was commenced. Owing to the shortness of the shaft of the femur rotation was exceedingly difficult.

After the ligation of the vessels the tourniquet was removed and but little oozing occurred. This was effectually controlled by hot moist compresses. A drain was placed at the acetabulum and brought out at the most dependent part of the stump. Muscle was coaptated to muscle, and the skin flaps approximated by catgut. Retention sutures of silkworm gut were also inserted. But little shock ensued and convalescence was rapid.

Another case in which the writer made use of the mattress pin was one of amputation at the shoulder joint. Miss S., aged 18, residing at Delaware, Ohio, was brought to St. Anthony's Hospital, April 29, 1897, suffering from gangrene of the left hand and forearm. Two weeks previous to her admission to the hospital the parts were caught in a steam-laundry roller and badly mangled.

Disarticulation at the shoulder-joint was performed April 30, the pins being used with complete satisfaction. No blood was lost until the last stage of the operation was reached. The principal vessels having been ligated, the tourniquet was removed and the flaps partly brought together, when suddenly a most violent capillary hemorrhage occurred.

Much difficulty was encountered in arresting this, but by means of continuous pressure it was finally controlled. Notwithstanding the great loss of blood, the patient evinced no shock and convalesced nicely. It was afterwards learned that she was one of the so-called bleeders.

New Instrument.

SPRAYING AND INSUFFLATING THE ACCESSORY NASAL CAVITIES.

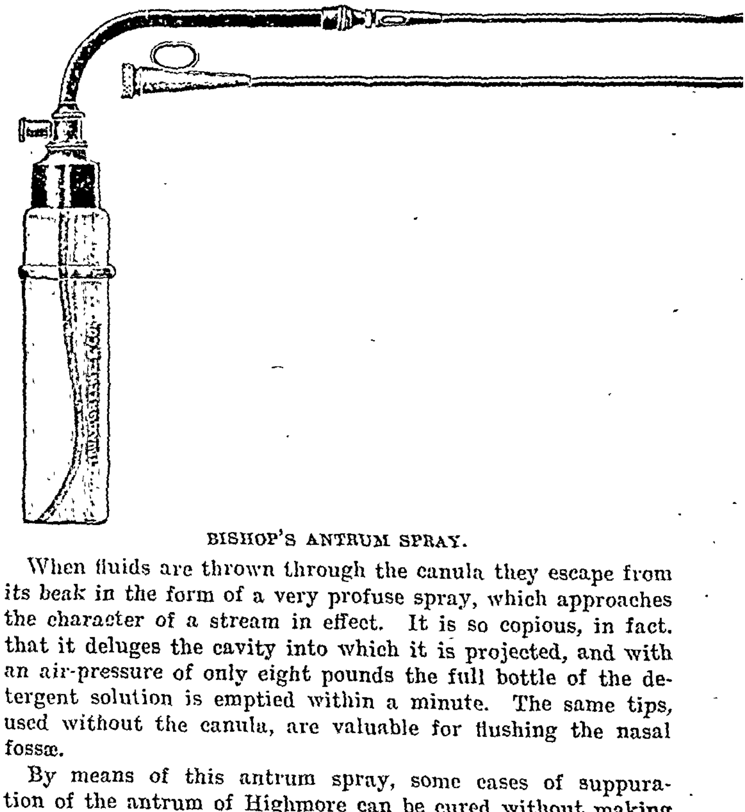
S. S. BISHOP M.D.
CHICAGO.

In suppuration of the cavities connecting with the nose the question of effectively cleansing and medicating them is a serious one. The ordinary nasal douche and sprays are inefficient. It is necessary that generous quantities of detergent solutions shall not only reach the affected parts, but that they shall flow over them with sufficient force to dislodge and carry away the offensive discharges.

The writer has devised a combination of canula and spray tips, shown in the accompanying illustration, which render satisfactory service. They are an adaptation of the Davidson atomizer fitted with spray tips having very large openings, and the outer tip being turned to fit closely into the conical opening of a special canula. The latter is made of silver, and is practically a modification of the Eustachian catheter. Instead of having the beak curved on the arc of a large circle, like that of the catheter, it is bent on the arc of a very small circle, so as to allow of its introduction into a narrow space.

This arrangement of the beak is required for the purpose of introducing it into the maxillary antrum, either through the ostium maxillare, or through an artificial perforation, for instance the opening made by way of the socket of a tooth.

The outer spray tip is so nicely adjusted to the conical mouth of the canula that there is no leaking at their junction, although the first ones made were defective in this respect; but a small piece of rubber tubing fitted over the outer spray tip, to join it with the canula, prevents the leaking.



BISHOP'S ANTRUM SPRAY.

When fluids are thrown through the canula they escape from its beak in the form of a very profuse spray, which approaches the character of a stream in effect. It is so copious, in fact, that it deluges the cavity into which it is projected, and with an air-pressure of only eight pounds the full bottle of the detergent solution is emptied within a minute. The same tips, used without the canula, are valuable for flushing the nasal fossæ.

By means of this antrum spray, some cases of suppuration of the antrum of Highmore can be cured without making an artificial opening, but the apparatus is just as effective for washing out the antrum after an operation. By rotating the beak of the canula, introduced through the artificial opening, the walls of the cavity can be thoroughly cleansed and medicated, as I have demonstrated many times.

If the canula is to be used in the ostium maxillare, the opening of the antrum is first located, the canula is introduced, and the latter is then marked at the point corresponding to the tip of the nose. This mark, in any given case, facilitates the introduction of the canula afterwards.

The same apparatus is useful in treating suppurative inflammation of the ethmoid cells, the beak of the canula being directed upwards so as to throw the coarse spray into the cells. Some patients with disease of the frontal sinuses have claimed that they could feel the spray from the canula enter the sinuses. I have not felt certain, however, that they were not mistaken.

After cleansing the suppurating surfaces, various powders, such as boric acid, aristol and nosophen, are blown through the canula to the diseased parts. When used as an attachment to the powder-blower the canula must be dry, hence it is advisable to have more than one for use in the combined wet and dry treatments.

HOSPITAL MANAGEMENT.

It seems that in England a disagreement between the managers and the medical staff at the National Hospital for the Paralyzed and Epileptic[1] has resulted in a free, general discussion of the question of hospital management, with particular reference to the relations between the lay managers and the medical staff. The *Practitioner* devotes its number for June to a "symposium" on the subject, the opinions of a considerable number of representative persons interested in hospitals in one capacity or another having been secured. The vital question is whether hospitals should be wholly under lay management or whether the medical staff should not also have a voice in the government. Mr. Burford-Rawlings[2] set up the claim that the medical element should be entirely excluded from any part in hospital government. The reasons advanced by the gentleman in support of this view can not be considered as reflecting much credit upon his conception of the true mission of the hospital and the relations of medical men to its work. At all events, his contentions would not find many supporters among interested persons conversant with hospital matters in general in this country. The symposium in the *Practitioner* may be summarized as an absolute and sweeping condemnation of the Burford-Rawlings theory of hospital management. Among others, Prof. Clifford Allbutt takes a decided stand against the so-called "lay supremacy" in hospitals, and comments upon the condescending attitude seen in some managers toward the physicians, an attitude which we in this country observe more particularly in the politician, who for a brief period finds himself "interested" in the management of the county or city hospital. The opinions collected by the *Practitioner* are strongly in favor of adequate medical representation on the governing bodies of hospitals. It is quite evident that the highest degree of success, in the broadest sense, will be attained in hospital work only when the fullest sympathy and harmony obtain between the managers of the financial and other matters and the men entrusted with the actual care of the patients. The exact manner in which this sympathy is attained does not matter so much, provided there is opportunity for it to grow and develop. A hospital in which there is lack of real co-operation between the managers and the medical staff is like a house divided against itself. There are so many elements essential to success in hospital work of which the lay managers can have no idea, that they should be happy to turn over certain things entirely to the medical men, and there are other questions of diverse kinds which the medical man is not so well fitted to handle as the man of affairs. The influence of medical men is especially needed in order to overcome the idea, often prevalent among laymen, that admirable buildings, well-prepared food, smart nurses, and the requisite number of patients constitute the essentials for a successful hospital. These things are well enough; but the one thing needful to bring out of them the greatest service is encouragement of the scientific spirit in the medical staff.

NERVOUS TACHYPNEA.

The act of respiration may be modified by a variety of influences; thus, it is lessened in frequency by opium and its derivatives, rendered irregular by uremic poisoning, and increased in frequency by all states attended with deficient hematosis. The last-named condition is known as dyspnea. When the demands on the respiratory function are lessened by reason of an over-supply of oxygen, apnea results. Mere increased frequency of respiration, occurring in paroxysms, or constantly with paroxysmal exacerbations, but unassociated with organic disease, is known as tachypnea, and it is not an uncommon manifestation of neurotic disorders, particularly hysteria and neurasthenia. An analysis of forty cases of this character, observed among a total of 1155 cases of various neuroses, has been made by Dr. Reckzeh.[1]

The term tachypnea was restricted to cases in which the respiratory frequency was forty or more in the minute, and all cases were excluded in which the condition was not purely neurotic and functional, but dependent on organic disease. Fourteen of the cases occurred in males, and 26 in females. In the former, the accompanying nervous disorder was either neurasthenia or traumatic neurosis; in the latter, hysteria, with the exception of 2 cases of exophthalmic goiter and 2 of profound neurosis. The men were from 18 to 44 years of age—with an average of 26.54; the women, from 15 to 52—with an average of 23.12.

With regard to etiology, heredity was found to play an important part, seven cases exhibiting hereditary predisposition, sometimes direct, at other times indirect. In other cases, the resistance of the nervous system had been lowered by somatic or psychic influences, such as alcoholism, traumatism with concussion, mental depression, anger, fright, functional disorders of the heart, gastro-intestinal disorders, diseases of the sexual organs, sexual excesses and abuses.

Respiration was moderately accelerated and superficial continually in 19 cases, with slight paroxysmal tachypnea in 11 of these, and severe in 8. In 5 other cases there was marked tachypnea continually, with paroxysmal exacerbations; and in 16 there occurred attacks of tachypnea, mild in 8, and severe in 8, the breathing at other times being normal. The respiratory rhythm was unaffected in so far as expiration followed inspiration without a pause, although the relation of the first to the second was as 1 to 1, instead of 7 to 6. The onset of the attacks of tachypnea was always sudden, while their subsidence was more or less gradual. The type of respiration was generally costal; the vital capacity of the lungs was usually low.

---

[1] See our "London Letter."

[2] Nineteenth Century, April.

[1] Berl. Klin. Wochenschrift, 1901, Nos. 17, 18 and 19.

No satisfactory explanation has been given for the occurrence of the attacks of tachypnea. It is thought, however, that the condition may be dependent on irritation of the vagus, resulting from psychic or other central or peripheral influences. This takes place in health, but under the circumstances in question it is more readily brought about.

The diagnosis of nervous tachypnea depends upon the exclusion of disease of organic character capable of causing increased frequency of respiration, and the presence of other neurasthenic or hysteric symptoms. The prognosis of the condition itself is good, although influenced by that of the underlying disorder.

The treatment is in part symptomatic, with such remedies as morphin, bromids, sulphonal, antipyretics, cardiants, and ice; and partly causal, directed to the relief of the neurasthenia or hysteria, with valerian, hydrotherapy, electricity, etc.

YELLOW FEVER AND MOSQUITOES.

For that final proof by experimentation of the cause of disease and its *modus operandi,* or for the collection of irrefutable evidence of pathogenesis, extensive use of animals has been necessary. The environment and other conditions upon which the proof depends of questions subjected to investigation may be absolutely controlled in this manner and accuracy of detail obtained to such a degree that the accumulated data assume the exactness of a mathematical proposition. Nevertheless, for some diseases and for certain problems the difficulties have precluded the use of animals and public sentiment has prevented the employment of human beings; this has been especially true of researches upon some of the infectious diseases.

Reed and Carroll, and the corps of assistants under them, in their investigations of yellow fever, have boldly waived all precedents of this character and have made use of human beings in experimentation with a success, in some respects, hitherto unparalleled. Without entering into the humanitarian phase of this procedure, except to note that in all instances the individuals experimented upon were "fully informed as to the nature of the experiment and its probable results," it is of interest to learn that the importance of the conclusions accruing from such courageous researches are in thorough accord with the novelty of the methods employed. The experiments in which human beings have been utilized and controlled in manners fully as precise as those of any animal experiments, have had as their product up to the present time, two conclusions; the rejection of the bacillus icteroides of Sanarelli as the cause of yellow fever, and proof of a connection between this disease and mosquito bites.

In an interesting summary of the work of this board,[1] Surgeon-General Sternberg reviews the familiar facts pertaining to the geographic and climatic prevalence of yellow fever with regard to its transmission by mosquitoes.

The failure of the experiments of Carlos Finlay, who first suggested this transmission, have been found to depend upon the length of time necessary for the "germ of yellow fever to develop in the bodies of the mosquitoes after they have bitten individuals afflicted with the disease. From this fact the thought at once intrudes that the parasite of yellow fever may be of a protozoan nature and allied to the organisms of malaria. In May of this year, Dr. Reed reported that yellow fever had been successfully conveyed to twelve human beings by mosquito bites. Some support to the mosquito transmission has been furnished by the inability to transmit the disease by experiments with clothing and bedding contaminated with vomites, excreta, etc., of the fever stricken; this has had as its corollary, that fumigation for prophylaxis is only of value as an insecticidal measure, and instructions to this end have been incorporated in a circular issued by the Chief Surgeon and Commanding General of the Department of Cuba, upon the approval of Surgeon-General Sternberg. It might be as well to direct investigation to the discovery of curative or abortive methods of treatment, as to the detection of the specific organism, for in some infectious diseases such treatment has long been highly useful, notwithstanding ignorance of the germs, e. g., hydrophobia and smallpox; moreover, the organism of yellow fever may, as hinted by Sternberg, be ultra-microscopic; it should be remembered[2] that Nocard and Roux, in their work upon pleuro-pneumonia of cattle, found an organism that was barely visible with a magnification of 2000 diameters. Finally, it is to be hoped, that by the use of collodion capsules, or some other equally ingenious technic, animals may be made susceptible to inoculation experiments and the use of human beings relinquished.

THE IDENTITY OF VACCINIA, COWPOX AND SMALLPOX.

It was the belief of Jenner that vaccinia, cowpox, and smallpox were expressions of the same disease; but this view has been warmly contested, and one of the early objections against the utility of vaccination consisted in the argument that one could not hope to confer protection from one disease by inoculation of another. This contention seemed supported by the difficulty encountered in transmitting smallpox from man to cow. Nevertheless, this has been accomplished in a number of instances. The inference seems justified, therefore, that by reason of certain biologic peculiarities, the cow is capable either of resisting entirely infection with the virus of smallpox, or of so modifying the latter that an attenuated form of the disease develops; and it may be concluded that the disease appeared the earlier in man, and from him was conveyed to the cow. The comparatively mild character of the disease when human beings were inoculated with smallpox for protective purposes seems not entirely without significance in this connection.

---

[1] Yellow Fever and Mosquitoes. The Popular Science Monthly, 1901, July.

[2] Journal A. M. A., xxxiii, p. 1117.

Believing it not improbable that much of the cowpox in the prevaccination period was derived from the inoculated form of smallpox, rather than the ordinary variety, Dr. S. Monckton Copeman,[1] one of the ablest and most ardent of contemporaneous investigators in the subject, undertook to obtain for purposes of experiment virus from Nubia and certain parts of India where inoculation of smallpox is still practiced; but without success. However, he found that the monkey is susceptible to smallpox, the various phases of which in this animal closely resemble those observed in man; and accordingly he inoculated some monkeys, and from them successfully conveyed the infection to calves, with the development of lesions indistinguishable from those of typical vaccinia, although calves could not be infected with virus directly from human beings. Further, he was able to vaccinate successfully children with lymph from the inoculated calves, without any generalization of the eruption or the development of any bad symptoms. It would thus appear that it is necessary for some change to take place, either in the virus of smallpox or in the condition of the calf before inoculation of the latter by the former can be effected. The observation, further, lends support to the view that smallpox, cowpox, and vaccinia represent varying grades of intensity of the same infective process.

VITALITY AND CHEMISM.

In the issue of *Science*, June 15, the late Dr. Joseph Le Conte notices the fact that seeds exposed to intense cold (—180 to —250 F.) do not lose their power of germinating, and suggests that as chemical action is arrested at such temperature, life may be a form of energy akin to chemism. He, therefore, attributes life to a particular molecular arrangement, the extreme cold acting by temporarily changing this molecular constitution. This may do for a hypothesis, but it will require some at present apparently impossible research for its verification. His admission that life is a form of energy seems hardly warrantable with our present knowledge; it certainly does not come under any law of the correlation of forces; it is not convertible into any other form of energy. Le Conte says: "The essential nature of life, as of all energy, is activity; but there is a necessary underlying condition, i. e., a peculiar molecular constitution, which may be called potential life." It seems much more natural and reasonable to recognize in vitality a still more ultimate agency than chemism, which seems itself to act under the guidance of this vital principle, as it may more properly be designated, rather than a force or form of energy, and to admit its as yet mysterious and unexplainable nature. To claim that, because chemism also survives extreme exposure to cold, life must itself be an analogous force, appears to us a begging of the question. The possibilities of the vitalized cell do not appear to us explicable by any known law of physics or chemistry as yet discovered.

A PROOFREADER'S BLUNDER.

Josh Billings said that the difference between a blunder and a mistake is that, when one takes another's umbrella and finds that it a better one than his own, "that's a mistake," but when the umbrella is poorer, "then it's a blunder." Probably the other fellow would not agree with him. Whether to call the error in proofreading which occurred in this journal last week a blunder or a mistake we are not decided. As there was no harm done by it and as it probably caused a good many smiles, we are inclined to call it a blunder. The title of the leading article as it appeared in the table of contents read: "Poverty and Pregnancy, their Cause, Prevention and Cure," and as the author, whose name followed, is one of the oldest, best known and most respected members of the profession, there was probably a good deal of curiosity manifested on the part of some to know what ultra-Malthusian ideas would be found in the article. While "poverty and pregnancy" are quite likely to be found together, the two could hardly be considered together in regard to their cause, prevention and cure. As a rule typographical errors are explainable, but it is hard to explain how the word "pregnancy" could be mistaken for "degeneracy"; we shall not try, but simply call it one of the blunders of the Fourth of July. As misery loves company, there is a certain amount of pleasure in reading in the current number of our staid and respected contemporary, the London *Lancet*, an apology for using the words "a sour correspondent," which it insists should have been "as our correspondent."

THE COMMITMENT OF THE INSANE.

The newspapers have recently devoted some of their news and editorial space to a case in which an alleged lunatic was liberated by an Indiana court decision as not insane, and have dilated upon the occurrence as a proof that under existing laws sane persons are liable to be committed to the "living death" of asylum existence. There is nothing that more quickly stirs up the public than such a charge, and there has been an evident tendency to make the most of it. Without regard to the merits of the particular case or to the peculiarities of Indiana laws, it may safely be said that the danger of sane persons being long confined in public asylums is a minimal one. It seems to us also that the presumption is all in favor of the insanity of a person detained in an asylum under presumably competent and honest medical officers, however the courts may decide. Dangerous lunatics have been released by judges and juries as not insane and the same individuals have been recommitted by judicial procedure almost immediately as a measure of public safety. In other cases suicides, murders and other dangerous acts have quickly followed their release. In fact there is nothing less infallible than judicial decisions as regards insanity, that is, as regards its existence or non-existence in individual cases. In states where a judicial proceeding is required for commitment it is possible for perfectly sane persons to be found insane, and vice versa. The predilections, however, of courts and juries rarely permit the first error, while the latter one is probably frequent enough. There is a very serious possible danger of the enlargement of unsuitable cases in any popular agitation in regard to the supposed confinement of sane persons, and judges and juries should realize their responsibility and make sure by fully competent testimony as to the fitness for absolute liberty of anyone they order released.

---

[1] British Medical Journal, May 11, 1901, p. 1134.

TYPHOID FEVER AND DIPHTHERIA.

As pointed out by Manges,[1] the development of diphtheria in the course of typhoid fever is probably often overlooked, principally on account of the stupid condition of the patient and because the physician does not often feel called upon to make thorough examinations of the throats of his typhoid fever patients. The older literature on typhoid fever contains frequent reference to pharyngeal and laryngeal complications of a diphtheric character, at least in the anatomical sense. While so thorough a writer as Curschmann, in 1898, practically denied the occurrence of true diphtheria in typhoid fever, several instances of this kind have been recorded both before as well as after Curschmann's expression of his views, more particularly by American writers, the diagnosis being fully verified by bacteriologic and cultural tests. Manges reviews these cases, adding six of his own in which the diagnosis of diphtheria was corroborated by cultural methods. Curschmann's statement is consequently incorrect. It is of importance that the possibility of true diphtheria developing in the course of typhoid be generally recognized, both for prophylactic and therapeutic reasons. Diphtheria antitoxin is borne as well by typhoid fever as by other patients, and it should be promptly administered, when necessary, in typhoid fever, so as to remove as thoroughly as possible the added danger of diphtheria, which does not seem to have any special influence one way or the other upon the clinical course of the typhoid fever itself. In many of the cases of mixed infection, especially the earlier ones, death resulted; in some instances the existence of diphtheria was not recognized until at the postmortem.

THE ETIOLOGY OF NOMA.

The etiology of noma has been made the subject of frequent inquiry in recent years, but the results have been otherwise than uniform. This is probably unavoidable on account of the large numbers of various kinds of organisms necessarily freely present in areas so exposed as those usually attacked by noma. It is true, however, that in several instances of noma competent investigators have demonstrated the presence of diphtheria bacilli. Beginning with Bishop and Ryan, in 1895, who described a pseudodiphtheria bacillus, or a true diphtheria bacillus of greatly reduced virulence, Freymuth and Petruschky, in 1898, found diphtheria bacilli associated with two cases of noma, one of the genitalia and one of the alveolar process. Both of these cases were cured by the use of diphtheria antitoxin. And now comes Walsh[1] with a report of eight cases of noma, in all of which he found B. diphtheriæ, as determined by the usual tests now in vogue. Most of these cases had measles, the disease which most frequently is succeeded by noma. Walsh points out that diphtheria is often seen with and after measles. In the St. Vincent's Hospital, from which his cases are taken, diphtheria and noma are also not infrequently associated. Walsh concludes that true diphtheria bacilli are found in many cases of noma, and that as noma is a form of gangrene it is not unreasonable that the diphtheria bacillus is the primary cause, at least in some cases, the putrefactive softening resulting from the growth of saprophytes. He thinks that when other pathogenic microbes, capable of causing necrosis, are found, then it may be that they are the primary excitants. A larger number of cases must be studied before the unity or multiplicity of the etiologic factor in noma may be definitely settled. The views of Walsh seem to harmonize well with the results of the bacteriologic observations so far, and if we grant that the bacillus of diphtheria is the cause of at least some cases of this destructive disease it at once follows that diphtheria antitoxin should be freely used in all cases of this kind, with a view to arresting the necrosis at as early a stage as possible in those instances started by the diphtheria bacillus.

THE MODE OF INFECTION IN ANCHYLOSTOMIASIS.

Anchylostomiasis is caused by a parasitic worm, the uncinaria duodenalis or anchylostomum duodenale, which inhabits the upper part of the intestine and produces, by removal of blood and possibly by intoxication, an anemic disease of extraordinary frequency in some parts of the world, especially Egypt, Italy, India, and also elsewhere. This disease is known also as Egyptian chlorosis, brickmaker's anemia, mountain anemia, miner's cachexia, etc. In the United States we are apparently free from the infection; at all events no observations have been made upon the disease in this country, except possibly in some of the southern states. The diagnosis is made by finding the eggs in the stools of persons with chronic anemia and wasting as well as more or less well-marked intestinal disorders. The mode of infection is supposed to occur through the drinking water, because the larvæ develop in moist earth, whence they may readily enter the sources of water-supply. In Egypt the disease is very common in those that work in damp soil, and, as indicated by the synonyms mentioned a moment ago, workers in the earth seem subject to the infection. Recently, Looss, of Cairo, has suggested another mode of entrance, namely through the skin. He found that when suspensions of larvæ are allowed to dry upon the skin there quickly results an area of redness and burning. The intestinal infection developed in his own case under circumstances that, he states, absolutely exclude entrance by the mouth, and while he was working with the larvæ. The fact that the larvæ sink to the bottom in reservoirs of water does not seem to him to favor the mode of entrance ordinarily accepted. Looss placed a drop of larval suspension upon the skin of an extremity an hour before amputation and carefully examined the area afterward. It was found that the larvæ penetrate freely into the hair follicles; this accounts satisfactorily for their rapid disappearance from the surface of the skin. He promises future reports on further work on this interesting observation. If found to be true, this ability of the larvæ to enter the skin will account for the infection perhaps even more satisfactorily than the explanation heretofore offered; especially in the case of laborers who stand for hours in soft mud. But the course of the larvæ toward the jejunum and the reasons that determine their wandering and their localization here offer many interesting problems for research. Perhaps a similar explanation is applicable to other parasitic invasions not now fully understood.

THE PERSISTENCY OF PLAGUE.

An editorial in the *Journal of Tropical Medicine*[1] summarizes the present status of the plague in terms that are not altogether encouraging. Hong Kong is now passing through the seventh recrudescence, one that promises to be the worst yet experienced. Modern sanitation seems there to have met its match. In spite of specially favorable conditions this British outpost appears to be as vulnerable as any of the adjacent insanitary Chinese towns and villages. "From what is known of plague," the editorial states, "we must expect when once a town is infected, that recurrences are not only possible but that they will continue with an inveterate persistency, rendering the future, from a public health and commercial point of view, gloomy in the extreme." The plague in Capetown is also instanced as affording unpleasant facts. We have come to believe that Asiatics were especially susceptible to the disease and that the white race, with its better modes of living and more sanitary habits, would be almost immune. In Capetown, however, the whites suffer fully as much as the colored races, and it is the Chinese there who are comparatively least affected, and next to them the Malays. Habits no more than race appear there to govern the spread of the infection, and sanitation has thus far done little effective work in checking it. From these and like facts it seems there is little ground for any complacent sitting down and waiting, with the belief that any section is safe. We evidently do not know yet all the resources and methods of the destroyer, and any false sense of security where the pest has apparently disappeared may have most disastrous consequences. It has reappeared in Honolulu notwithstanding the very energetic measures taken against it, and may do so elsewhere where the measures have not only not been so thorough, but have been embarrassed by an ostrich policy of suppression of facts. These are possibilities to be seriously considered, and only eternal vigilance can be regarded in any exposed section as the least price of security.

AN ENCOURAGING OUTLOOK IN MEDICAL LEGISLATION.

Medical practice acts are gradually "going through the mills" of the supreme courts, and are generally coming out all right. One of the most recent decisions is that of the Ohio supreme court refusing a mandamus to compel the State Board of Medical Registration to recognize the diplomas of the Hygiea Medical College, of Cincinnati. The court rejected the plea that the grant of the power to determine what medical colleges were in good standing was unconstitutional, since that point had already been decided by another decision If it were void on this ground, moreover, it would be highly improper for the court to compel the board to exercise it as regards this particular institution. The charge of prejudice does not appear to be sufficient ground for mandamus in this case. The proper scope, the decision says, of a mandamus, against an official board, is to command the performance of acts which the law has specially enjoined upon it as a duty resulting from the office. Unless the duty is so enjoined the remedy is inappropriate. Search of the statutes reveals no provision authorizing the application of a medical institution to be recognized as in good standing or compelling the board to act on it. It is only when a diploma is presented that the action of the board can be invoked. Whether, then, a mandamus would lie on the refusal of the board to grant a certificate, must depend on the facts of each case. Such cases can not be covered by a general order to grant certificates to the graduates of any particular institution, for unless an application is made the duty of the board to grant does not arise. And then the seeking the remedy for a refusal belongs to the applicant as the party directly interested, and not to the college issuing the diploma, whose interest is only remotely affected. The statute does not define what shall constitute a medical institution in good standing; that is left to the judgment of the board. It is unnecessary to inquire here whether there may be cases where the courts would undertake to correct or control its judgment. It is clear that the standing of a medical college within the meaning of the statute is not to be determined alone from the course it has prescribed for graduation. The statute imports, at least, that it shall be one that has established a favorable reputation in the medical profession. The board should not be required to recognize one that, from its brief existence or the novelty of its teaching, in its judgment has not acquired such reputation, and much is necessarily left in this respect to the sound discretion of its members, who, it is assumed, will act as their position requires, fairly and justly to all concerned. This decision, of which the above are the leading points, is a valuable one to our Ohio confrères, as establishing the validity of the law, and also affords a useful precedent for reference in other communities.

The French Government sends every year some young men, natives of Madagascar, to Paris for a two-year course in medicine, after which they return home to practice.

---

[1] June 15.

Medical News.

COLORADO.

Dr. Charles Denison, Denver, sails for Europe on the *Campania*, July 13, to attend the British Congress of Tuberculosis.

New Medical Law.—The effect of the new medical law is being felt. On June 16, a "doctor of psychology" was fined $50 and costs for practicing medicine without a license.

The National Hospital for Consumptives, Denver, has received donations of $25,000 from W. Guckenheim's Sons, of New York, and $5000 from S. Grabfelder, of Louisville, to be applied to the building fund.

Tuberculosis in Colorado.—Dr. Henry Sewall, Denver, in a report made to the state medical society, stated that in the sixteen months to May 1, 1901, 1674 deaths from tuberculosis were reported. In 970 cases the disease originated outside of Colorado. In 480 cases, the origin was not given. In 224 cases or 13.32 per cent. the disease originated in Colorado.

The Colorado Maternity and Children's Hospitals, Denver, were opened to inspection a short time ago. The staff of the new institution is as follows: Consultants, maternity staff, Drs. Thomas H. Hawkins, Francis H. McNaught, William P. Munn, William S. Bagot and Charles B. Van Sant; children's staff, Drs. Herbert B. Whitney, Seymour D. Van Meter, Eleanor M. Lawney, Melville Black, N. Harris Kirby and Frank E. Waxham. Visiting Staff, maternity, Drs. Frank W. Kenney, Seymour D. Van Meter and Laura L. Liebhardt; children's, Drs. Frank W. Kenney, F. P. Gengenbach and C. A. Graham.

ILLINOIS.

Dr. E. M. Sutton, Peoria, will spend his vacation in Europe. He will go on the *Umbria*, leaving New York on the 20th.

Dr. Arthur L. Hagler has been appointed on the staff of the St. John's Hospital, Springfield, in the eye and ear department.

Dr. Frederick C. Winslow, has assumed charge of the Asylum for the Incurable Insane at South Bartonville, near Peoria.

Physician Not Horse Doctor.—Judge W. G. Cochran has decided that a surgeon has not the right to practice as a veterinary in a suit brought by Dr. Max W. Barbour, of Arcola, against a race-horse owner for services rendered to one of his horses.

Chicago,

Dr. A. M. Corwin has resigned from the faculty of Rush Medical College.

Dr. Henry H. Mather, while playing golf, sustained a fracture of the right fibula.

Dr. Arthur Reynolds sails from New York, on July 13, for London, to attend the Congress on Tuberculosis.

Dr. Willis O. Nance will leave New York on Saturday, July 20, on the *Umbria*, for a six weeks' European trip.

Drs. Frank Billings and Robert H. Harvey leave this week to spend their vacation at Mackinac Island, Mich.

Travelers.—Drs. J. A. Robison and W. Byron Coakley have joined the army of European travelers and will attend the Tuberculosis Congress in London.

Dr. L. Blake Baldwin, who has been appointed professor of clinical dermatology in the College of Physicians and Surgeons, left July 1, for Paris, where he will spend three months.

The Chicago Lying-In Hospital has received a donation of $5000 from Abram Slimmer, Waverly, Iowa, for the erection of a new dispensary building, contingent on the subscription of $10,000 additional.

The College of Physicians and Surgeons has been formally deeded the West Division High School property, by the City of Chicago, the consideration being $186,000. About $40,000 will be expended on the building belonging to the college recently burned.

Northwestern University Medical School.—N. S. Davis, Jr., has been elected dean, and Arthur R. Edwards, secretary, of the faculty. Wesley Hospital, in close connection with the college, has been informally opened to the profession, and after complete equipment the formal opening will take place. The Hospital will accommodate 300 patients. Plans are completed and the money is raised for a $22,000 amphitheater and operating rooms at Mercy Hospital, with a seating capacity of 400. Drs. C. L. Mix and P. T. Burns have been appointed assistant professors of anatomy.

Changes in Medical Department of the National Guard.—The resignations of Major G. Frank Lydston, surgeon, and Lieutenant Elihu N. Elliott, assistant surgeon, assigned to Second Infantry, and of Lieutenant Norval H. Pierce, passed assistant surgeon, first ship's crew, Naval Militia, have been accepted. Dr. Buell S. Rogers has been commissioned major and surgeon, Dr. B. McPherson Linwell, captain and assistant surgeon, and Drs. Frank Webster Jay and F. Gregory Connell have been commissioned first lieutenants and assistant surgeons, and assigned to the Second Infantry.

Mortality and Morbidity.—Notwithstanding the high temperature of the past fortnight the mortality rate has not been materially increased. There were but 17 more deaths last week—and of these 7 were from sunstroke—than during the previous week, while the total was 20 fewer than in the corresponding week of 1900. Only the continued malignant character of the widespread epidemic of measles gives the Department any concern. There were 13 deaths recorded from this disease last week and the type of the malady shows no change. The Department repeats its warning to parents against exposing non-immune children to the contagion and again insists upon the necessity of strict isolation of all measles patients. The disease is especially prevalent and severe in the 27th Ward.

Increase of Suicides.—The recent enormous increase of suicides in this city has led the Commissioner of Health to request the Coroner to make special inquiry into the history of these cases with reference to the relation of influenza. In the following note to that official it is pointed out that "In the five years, 1871-1875, the suicides in Chicago were 12.6 per 100,000 of population. In the last lustrum, 1896-1900, there were 23.0 per 100,000. The increase—which has been quite general in all civilized countries during the past half-century—was very gradual in Chicago until about 1893, when they suddenly increased from 18.7 in 1890 to 23.8 per 100,000. Grip or influenza has been more or less prevalent in this city since the fall of 1889 and was especially prevalent in 1891. It is claimed that this disease profoundly affects the nervous system, causing all grades of mental disturbances, from simple melancholia to acute insanity. It is quite possible that the great increase in the number of suicides in 1893 was due to this effect of the grip epidemic of 1891 and that the general increase during the whole period, 1890-1900 is due to the same disease. What I wish you would do for me is to cause inquiry to be made in every case whether the suicide had ever had an attack of grip or influenza; if so, in what year; and had the fact ever been the subject of comment by the suicide or the family or associates. Please have these data noted on the Coroner's certificate so that I may have them properly compiled."

No Private Hospitals in Chicago.—The London *Lancet*, June 22, prints the following paragraph from its New York correspondent: "Novel Sanatorium in Chicago.—A sanatorium is about to be constructed in Chicago upon a wholly new principle. The medical men in that go-ahead city have for some time been dissatisfied with the means of accommodation which Chicago offers to patients from a distance who are desirous of placing themselves under the charge of practitioners there. There are many objections both on the part of physicians and patients to the large general hospitals and it seems that there are no private hospitals in Chicago. In consequence of this condition of affairs those who wish to be treated in the city are compelled to betake themselves to large hotels or to apartments. The big hotels are too noisy and apartments have, as a rule, some drawbacks. Besides, friends or relatives of the sick have not always been able to secure quarters near the sick bed. To remedy this unfortunate situation five physicians and surgeons of Chicago are preparing to build a large private hotel and sanatorium to cost $400,000 (£80,000). This combination of hotel and sanatorium is, it may be imagined, the first time that such a plan has been put into execution, and it is yet another tribute to the practical versatility of the Western American's brain." It will be news to the Chicago profession that there are no private hospitals in this city, or that it is necessary for patients to betake themselves to hotels when they come for treatment.

INDIANA.

W. T. Davis, Ehrmandale, has been fined $20 and costs for practicing medicine without a state license.

The President of the Red Cross Medical Society, Indianapolis, has been fined $25 and costs for practicing medicine without a license.

The W. B. Fletcher Sanatorium has been incorporated at Indianapolis with a capital stock of $50,000 by Drs. William B. Fletcher, Mary A. Spink, Urbana Spink and others.

Mears Memorial Library.—Dr. J. Ewing Mears, Philadelphia, proposes to establish a medical library and to found a home for the Marion County Medical Society in memory of his father, the late Dr. George W. Mears, who was a pioneer physician of Indianapolis.

New Military Surgeons.—Drs. W. Ruston Davidson, Evansville; Paul J. Barcus, Crawfordsville, and Jacob M. Hill, South Bend, have passed their examinations and been recommended for commissions as assistant surgeons in the First, Second and Third Infantry, respectively.

The physicians and surgeons of Anderson, owing to the numerous suits for alleged malpractice, have agreed to refuse all service in surgical cases unless the patient or his family signs an agreement releasing the surgeon from liability in the event of any unsatisfactory results.

KENTUCKY.

Kentucky School of Medicine, Louisville, held its annual commencement exercises, June 26, graduating a class of forty-three.

Hospital College of Medicine, Louisville, held its annual commencement, June 27, graduating a class of fifty-seven. Dr. Lewis S. McMurtry, president of the college, delivered the doctorate address.

Kentucky University Medical Department, Louisville, held its annual commencement exercises, June 25, graduating a class of nineteen. The address to the graduating class was made by Rev. George B. Eager, D.D.

Dr. W. E. Clark, who was convicted of manslaughter in January last, has been granted a new trial by the appellate court, June 22, because of the admission of certain evidence, the failure to admit evidence of defendant, and the instructions of the court.

MAINE.

The State Board of Health, at its annual meeting, re-elected Dr. Charles D. Smith, Portland, president.

Smallpox is prevalent in Bangor. Public vaccination has been ordered and strict quarantine is being enforced. Bangor has 8 cases of the disease, Milo 5 cases, Portland 1 case, and Lagrange and Dexter each 2 cases.

The Medical School of Maine, Brunswick, held its annual commencement, June 27. This was the last class to graduate under the three year rule. A class of thirty-nine received diplomas, and the doctorate address was delivered by Hon. Augustus F. Moulton, Portland.

Anatomical Material.—An act has been passed by the legislature requiring all public offices having charge or control over dead human bodies to notify immediately the Board of Distribution whenever unclaimed bodies come into their control, that the said board may take and remove such bodies to be used within the state for the advancement of medical education.

A "magnetic healer," of Portland, who had been notified by the secretary of the State Board of Medical Registration not to practice medicine without examination and registration and who nevertheless persisted, was indicted, tried and found guilty. The accused used the letters "S. R. S." after his name in his advertisements, and on being asked their significance, stated that they meant "*Silent Rubbing Specialist.*"

MARYLAND.

Baltimore.

Dr. Robert Hoffman sailed for Europe July 4.

Dr. Frederick Taylor has sailed for England.

Dr. Marie E. Thalwitzer has sailed for Europe.

Dr. James M. Crayhill will sail for England July 20.

Dr. Daniel Z. Dunnott will spend the summer at Plinhimmon, Ocean City, Md.

Dr. Harry Friedenwald left with his family, on July 4, to spend the summer in Europe.

Dr. John Ruhrah, who has been studying in the hospitals of Berlin, Vienna and Paris, is now in London. He will return to Baltimore, September 1.

Memorial to Dr. Jesse W. Lazear.—Those who were associated with the late Dr. Jesse W. Lazear at Johns Hopkins Hospital, are planning a suitable memorial of his life and services.

Mr. J. W. Middendorf has contributed $10,000 to the Charlotte Williams Hospital, of Richmond, Va. The institution is a memorial to a deceased daughter of Mr. John L. Williams, of the latter place.

Mosquito Extermination.—A company has been organized here to fight the mosquitoes. It is called the New Jersey Mosquito Exterminating Company. A small stipend will be charged for which the company undertakes to rid one's premises of the pest for the season.

The mortality of this city for the week ending July 6 was 451, the largest since records of deaths began to be made. This is the more remarkable because but two weeks before the mortality had been the smallest ever known. The intense heat lasting throughout the week, and on two days reaching 103 F., is accountable for this large figure. There were 78 deaths from sunstroke, 234 were under 5 years, and 89 over 60 years of age.

Dr. Howard A. Kelly and family are at the Colonial, Ocean City, Md.; Dr. Powhattan Clarke is at Chester, Nova Scotia; Dr. C. C. Bombaugh and family are spending the summer at Niagara-on-the-Lake, Ontario; Dr. H. C. McSherry is at Blue Ridge, Summit, Pa.; Dr. W. W. Russell is at Marine Villa, Cape May, N. J.; Dr. Alan W. Smith and wife are at Rehoboth Beach, Del.; and Dr. Henry Lee Smith is at the Blue Mountain House for the summer.

Fraud at Examination.—A case of fraud was attempted at the recent examinations before the Maryland State Board of Medical Examiners. A young physician, said to be a Philadelphian and graduate of the University of Pennsylvania, applied to the board for examination, giving the name of another physician, graduate of one the Baltimore schools, now practicing in New Jersey. The scheme was discovered and a detective put on the case. The only motive found was the alleged fact that one holding the Maryland certificate can get a New Jersey certificate without further trouble. The candidate was refused the Maryland certificate, though he received a high average.

Tablet to Dr. Jesse William Lazear.—At Trinity Hall Military School, Washington, Pa., on commencement day, June 18, a tablet to the memory of Dr. Jesse William Lazear, of Baltimore, was unveiled with appropriate ceremonies. It is inscribed as follows: "In memory of the virtue and self-sacrifice of Jesse William Lazear, M.D., of Baltimore, Md. Born May 20, 1866. Died Sept. 25, 1900. Prepared for college at Trinity Hall, 1880-4. Graduated at Johns Hopkins University, medical degree from Columbia University, Instructor at Johns Hopkins University, Assistant Surgeon United States Army. Died while investigating causes of yellow fever in Cuba. He gave his life to his country for the advancement of science. *Pro Deo et Patria.*"

MASSACHUSETTS.

Tuft's College Medical School held its annual commencement June 19, graduating a class of thirty-four.

Doctors Have Smallpox.—Dr. Charles B. Stevens and Dr. Campbell, of the staff of the Worcester City Hospital, and one of the nurses are ill with smallpox.

The Wage Earners' Hospital is to remove to Harvard and Albany Streets, Boston. Drs. George Van B. Buehler, Charles L. Ogden and Clarence M. Casselberry constitute the staff of the new hospital.

Franklin Hospital, Boston, was opened June 6. It has a capacity of about sixty beds, and is so arranged that patients can be cared for by their own physicians. Dr. R. Sherman York is in charge of the hospital.

Frost Hospital, Chelsea, held its annual meeting, June 21. Dr. Frederick S. Raddin was elected a member and secretary of the Medical Board. Dr. Charles H. Shackford was re-elected chairman of the board; Dr. Joseph B. Fenwick was elected admitting physician.

NEBRASKA.

Dr. John P. Lord, Omaha, has returned from a nine-months' tour of Europe.

Dr. Minerva M. Newbecker has resigned as assistant superintendent of the Hospital for the Insane at Lincoln. Her successor has not yet been appointed.

New Asylum Physicians.—Dr. William L. Carlyle, Hebron, has been appointed assistant physician of the Hospital for the Chronic Insane at Hastings, vice Dr. Woodward, resigned; and Dr. Alma J. Chapman, Hastings, succeeds Dr. Ewing, resigned.

Nebraska Anatomical Society.—By an act of the legislature, the Nebraska Anatomical Society has been formed in

Omaha, and will be given possession of all unclaimed pauper bodies in the state for distributon to medical colleges. The unclaimed bodies annually range from 300 to 500.

NEW MEXICO.

State Board of Health.—At a regular semi-annual meeting of the New Mexico Board of Health, held at Santa Fe, June 3, Dr. George C. Bryan, Alamagordo, was elected president, and Dr. Walter G. Hope, Albuquerque, secretary.

Consumptives Improve.—The Government Hospital for Consumptives at Fort Bayard reports 149 patients undergoing treatment, many of whom have so improved as to be able to return to duty. A majority of the patients show marked improvement.

Medical Examiners for School Teachers.—The president of the territorial board of health has appointed twenty-two physicians to examine school-teachers in accordance with the new law which provides that no one suffering from tuberculosis shall be allowed to teach school.

NEW YORK.

Jamaica Hospital.—At the annual meeting of the medical staff of this hospital, Dr. Philip M. Wood was elected president; Dr. Henri M. Auger, vice-president, and Dr. Austin J. Blanchard, secretary. Drs. Samuel D. Nutt, of Ozone Park, and William T. Scovil, of Richmond Hill, were added to the medical staff.

Census of Consumptives.—A census of the consumptives in the state is to be taken by Dr. Daniel R. Lewis, President of the State Board of Health. This census is only for the purpose of learning the number of consumptives in the state as far as possible, and the revealing of other facts relating to the disease, of importance to the profession.

Health Report.—There were 10,327 deaths in New York state during May, or 500 above the average for that month during the preceding years, according to the monthly report of the State Board of Health issued July 3. Smallpox has been reported during the month from 24 different points and in all there have been noted 32 new cases within the past month.

The Albany Medical College has made several changes in its faculty. Dr. Howard Van Rensselaer will have charge of the departments of materia medica and therapeutics, and the practice of medicine. Dr. Leo H. Neuman has been appointed clinical professor of the practice of medicine and Dr. J. Montgomery Mosher is now clinical professor of neurology and electro-therapeutics. As lecturers, Drs. Arthur T. Laird, on clinical microscopy, George E. Lochner, on gynecology, and Chas. H. Richardson, on surgery, were appointed.

Buffalo.

The Exposition Hospital has already treated 1600 cases.

Dr. Augustus Pohlman, instructor in anatomy at Cornell University, Ithaca, has gone to Freiburg, Germany, for special study in anatomy.

Buffalo Academy of Medicine.—The medical section, at a recent meeting, elected Dr. Harvey R. Gaylord chairman, and Dr. Harry Rooth secretary.

The United States Hospital Corps Camp at the Pan-American Exposition will prove of especial interest to physicians interested in seeing a model sanitary field hospital. There is a tropical, a summer and a winter ward.

The Buffalo Fresh-Air Mission has opened its hospital at Athol Springs for the summer season. At this hospital a large number of infants suffering from non-communicable disease and belonging to poor parents, are treated every summer and many are restored to health.

University of Buffalo.—The faculty and alumni association of the medical department of this University have established a Pan-American bureau of information for the exclusive benefit of the alumni who are to visit the Pan-American. The bureau has been opened in the library of the University at 24 High Street, near Main.

New York City.

Dr. Louis Fischer sailed for Europe on *La Bretaque*, June 27.

Dr. S. A. Knopf sailed for London July 10, to attend the British Congress on Tuberculosis.

Dr. Charles K. Briddon recently completed his twenty-fifth year as attending surgeon to the Presbyterian Hospital.

The Floating Hospital Services for the children of the poor has been begun for the summer season by St. John's Guild.

The Emergency Hospital connected with the Department of Charities, at Coney Island, is completely fitted up and has an ambulance service.

Five Brooklyn Physicians, who have been sued by a debt-collecting agency, declare that they signed the contract, under the terms of which they have been sued, under a misapprehension, and that the conditions of the contract are practically impossible of fulfillment.

Claim for Expert Services Allowed.—The claim of Dr. Jackson R. Campbell, Tombs physician, for $2250 on account of services as expert medical examiner, which was disallowed by Comptroller Coler, and was referred to the corporation counsel, has been ordered paid.

In the case of Herbert C. Wadman, a patient, who died at Manhattan State Hospital, the coroner's jury rendered a verdict that Wadman came to his death from chronic nephritis and acute mania, aggravated and hastened by broken ribs and injuries to the chest and head. The jury censured the management of the Manhattan State Hospital, exonerating the Bellevue Hospital authorities, and found that the injuries were inflicted by Attendant John Foley, and that keeper Michael Carroll was an accessory.

OHIO.

Dr. and Mrs. John Edwin Brown, Columbus, sailed for Antwerp on the *Vaderland*, June 26.

Mr. H. M. Hanna, Cleveland, has endowed a chair in the Medical School of Western Reserve University.

Dr. Reginald B. Leister has resigned from the staff of the Toledo State Hospital and will practice in Toledo.

Dr. J. M. Crawford, ex-minister to Russia, has been created Doctor of Laws by the Ohio University at Athens.

B. S. Slocum, a negro, was arrested on June 24 at Amanda, Fairfield County, charged with the illegal practice of medicine.

Dr. Fred L. Wilson, of the Athens State Hospital for the Insane, has resigned and will resume practice at Washington Court House.

New Laboratory.—The Laboratory of Clinical Microscopy, Medicine and Surgery, donated by John H. Brown, of Cleveland, in memory of his brother, and by Samuel Mater, to the Medical Department of Western Reserve University, Cleveland, who dedicated with appropriate ceremonies, June 12. Dr. Herbert L. Burrell, of Harvard Medical School, delivered the principal address.

Osteopathy.—A motion to advance the case of the State of Ohio vs. Gravitt was granted by the Supreme Court of Ohio last week. This case involves the question of the practice of osteopathy under the provisions of the law which took effect on July 1, 1900, and the granting of the motion insures a speedy hearing and decision of the case.

PENNSYLVANIA.

The estate of the late Dr. William H. Daly, Pittsburg, is estimated to be worth $250,000.

Rev. William A. Passavant, of Pittsburg, widely known as a philanthropist, and a worthy successor of his father in the establishment of hospitals in various cities of the country, died suddenly at Jummonville, July 1, from apoplexy.

Appropriations.—The following appropriations were passed by the Legislature, June 25: Free Hospital for Poor Consumptives, $110,000; Taylor Hospital, Lackawanna County, $15,000; Medical Department of Western Pennsylvania Hospital, Pittsburg, $100,000; Titusville Hospital, $10,000; St. Joseph's Hospital, Scranton, $1000, and Nason Hospital, Roaring Springs, $5000.

Philadelphia.

Dr. Thomas R. Neilson has been elected assistant clinical professor of genito-urinary diseases at the University of Pennsylvania.

The State Board of Medical Examiners held an examination June 18 to 22. Three hundred and thirty candidates for certificates to practice medicine were examined.

Appropriations.—The legislature has made the following appropriations to Philadelphia medical institutions: Medico-Chirurgical Hospital, $190,000; Jewish Hospital, $10,000; St. Joseph's Hospital, $10,000; University of Pennsylvania, $25,000, and University of Pennsylvania Hospital, $58,000.

Prof. W. W. Keen, of Jefferson Medical College, has been granted two years' leave of absence and Prof. J. Chalmers DaCosta will do his work, together with his own, both in the college and in the hospital. This additional work necessitates Dr. DaCosta's resignation from his position on the surgical staff of St. Joseph's Hospital, and Dr. Charles F. Nassau has been appointed to fill the vacancy.

VIRGINIA.

Old Dominion Hospital.—Ground was broken for the new Old Dominion Hospital, Richmond, June 22.

Dr. Samuel A. Hinton, Petersburg, has been appointed city physician, vice Dr. Hugh Stockdell, deceased.

The Isle of Wight County Board of Health has been organized with Charles H. Hart, Suffolk, president; Dr. Leslie C. Brock, Smithfield, secretary.

Winchester Memorial Hospital.—Mrs. Lewis H. Hyde, of New York, has contributed $5000 toward the building fund of this hospital. Of the $15,000 required, $7000 has now been raised.

WISCONSIN.

The New Norwegian Luthern Hospital at La Crosse was wrecked during a tornado, June 28.

Dr. Horace M. Brown, Milwaukee, has sailed for London, where he will attend the British Congress on Tuberculosis.

The Alumni Association of Milwaukee Medical College has been incorporated by Drs. Lawrence Hopkinson, Ernst J. Panetti and Eugene D. Regan.

GENERAL.

Health Board and Laboratory for Manila.—The Philippine Commission has passed bills establishing a Government biological and chemical laboratory. A Board of Health, consisting of commissioner, sanitary engineer, chief inspector, laboratory superintendent and secretary, has been formed. Stations for the supply of vaccine virus will be established wherever necessary in the provinces.

War on Mosquitoes.—The Marine-Hospital Service has instructed its medical officers to aid in the extermination of mosquitoes and fleas, and to take every precaution possible to keep the pests from the hospitals and quarantine stations. It is required that all pools of water near stations of the service be covered with petroleum. Patients with infectious diseases must be protected by wire netting. The army quartermasters also have arranged for a supply of kerosene, which is to be used on all stagnant water within the confines of military posts.

Dr. S. Weir Mitchell, who, as we announced last week, has just returned from a trip around the world. Evidently the Doctor has the reputation of being a worker, for a newspaper asserts that six long novels, forty-nine sonnets, 103 quatrains and several other poems, not to mention four books of sketches, a treatise on nervous diseases, fifteen or twenty short stories, were dashed off by him at odd moments during his trip. All these precious works, we are informed, are now in the possession of Richard Watson Gilder, who has hired eight detectives to watch the stuff.

A New Journal.—The first issue (June) of a new psychiatric journal, *The Journal of Mental Pathology*, has been received. It is published in New York under the editorial management of Dr. Louise G. Roubinovitch, with Drs. Magnan, Joffrey, Raymond, Regis and Morell abroad, and Drs. Mills and Hughes, of this country, as editorial collaborators, and a very extensive staff of contributors from all parts of the world. The initial number contains articles by Drs. Marie, of Paris; Ferrari, of Italy; E. A. Spitzka, of New York, and the editor, with selections, editorials and book notices; it presents a very creditable appearance. From the reputations of the collaborators and contributing staff, we shall look for high-class work in the articles appearing in this new journal; the character of those in the present issue promises well for the future.

CANADA.

A death from tetanus following vaccination is reported from Brantford, Ont.

Charity Bequests.—By the will of the late Senator Villeneuve, Laval University gets $25,000, Notre Dame Hospital, Montreal, $5000, and the Catholic Orphan Asylum, $5000.

Dr. A. T. Stanton, late of the house staff of the Toronto General Hospital, has been appointed surgeon of the C. P. R. steamer *Empress of China* of the Pacific fleet. Dr. Stanton left last week for the Pacific Coast.

Militia Dental Corps.—At the annual meeting of the Eastern Ontario Dental Association held in Ottawa, on July 4, a resolution was passed requesting Dr. Borden, minister of militia, to take steps to have a dental corps appointed in connection with the Canadian Militia.

Montreal is once more free of smallpox; quarantine was raised on the last house last week, and there are now no houses quarantined in that city. There are only three or four patients at the smallpox hospital, and it is expected they will be released in the course of a few days.

Dr. Montizambert, Director-General of Public Health, and Dr. McEachren, chief veterinary inspector for the Dominion, have been delegated by the Canadian government to attend the conference to be held in London, on July 22, to consider the question of prevention and cure of tuberculosis.

The Royal College of Dental Surgeons assembled in convention in Toronto last week, there being a large attendance of outside members. Dr. Walter Willmott, of Toronto, addressed the convention on the use of the *x*-ray in dentistry, and showed the importance the rays were in the profession of dentistry.

Montreal General Hospital.—During the month of June there were 262 admissions to this hospital, 256 discharges and 15 deaths. The average number of patients daily in residence was 167. The average of typhoid fever cases was 15. During the hot spell there was a large number of cases of sunstroke and heat prostration, but there was only one death from this cause. There is at present a great demand for trained nurses in Montreal, and the Training School is constantly besieged with enquiries. The graduates of this institution now number 180.

Cottage Hospital Scheme.—The idea of special collecting cards in connection with the Cottage Hospital scheme has proved very successful, and Lady Minto is pleased with the results so far. Nearly $20,000 has reached her excellency in this way from various parts of the country, and the countess is especially delighted with the work of the ladies of Montreal. In London, Ont., the scheme of collecting has been taken up by a special committee, and there excellent progress has been made. A rather curious circumstance is that the responses from Winnipeg are almost nil. Throughout the West around Regina and Saskatchewan, the scheme is being taken up with interest, and even from far-off Yukon subscriptions are coming in.

FOREIGN.

The Berlin University is planning an institute for radiotherapy. Professor E. Lesser is to be placed in charge.

The Plague at Rio Janeiro.—The four cases of bubonic plague recently found in Rio Janeiro were all brought from Oporto, Portugal.

The Plague at Capetown.—The total number of plague cases up to July 7 has been 760. The deaths have numbered 361, including 65 Europeans.

Glasgow University Honors Germans.—The University of Glasgow, on the occasion of its 450th anniversary, conferred honorary degrees on Quincke, Mikulicz and Kronecker, of Germany.

Reorganization of Turkish Medical Colleges.—Professor Rieder, of Bonn, and Dr. Deycke, of Hamburg, have been reorganizing the medical schools in the Turkish empire, at the request of the sultan. Rieder has been appointed general inspector of medical education.

Professor von Leyden's Jubilee.—The twenty-fifth anniversary of Professor Leyden's incumbency of the chair of medicine at Berlin was celebrated with much ceremony, June 8, by his friends and pupils. He was the successor of his master, L. Traube, and has worthily sustained the traditions connected with the chair.

Memorial to Pettenkofer.—Munich is planning a statue of Max von Pettenkofer, and also the erection of a Pettenkofer building, to contain a museum of articles connected with Pettenkofer's life and services to hygiene and sanitation, and also rooms for meetings of medical and other scientific societies, and a library. The committee that has the matter in charge is formed of the municipal authorities and chiefs of the Institute of Hygiene, etc.

Honors to the Memory of Physicians.—A portrait bust of Theodor Meynert was unveiled at the Vienna University, May 19, nine years after his death. The memorial was erected by the government in honor of Meynert's discoveries and achievements in psychiatry. Berne is preparing to honor in the same way the memory of A. von Heller, the famous scientist and physician of the eighteenth century, who, as simultaneous professor of surgery, anatomy and botany, conferred such luster on the University of Goettingen.

The Virchow Fund.—The amount raised for this fund was 78,000 marks when it was first presented to Virchow in 1881, on his sixtieth birthday. According to his wish it is devoted to anthropologic, ethnologic and prehistoric research. Six scientific expeditions have received appropriations from the fund and their discoveries have been duly published and illustrated in the Transactions of the Berlin Anthropological Society. The excavations were in the Caucasus, Malacca and in Cyprus. The expenses of Cetti's fasting test under the supervision of Senator, Zuntz and Munk were also defrayed from the fund, and the important scientific researches of Stuhlmann, Mies and Meslort on prehistoric biology, etc., published. The fund has been increased by various gifts until it is now 137,000 marks. The committee in charge are anxious to have it reach 200,000 marks, or about $80,000, by October 13, Virchow's eightieth birthday, as mentioned in the appeal published last week, p. 40. We learn from our exchanges that, during a recent windstorm, he was hurled against a tree and severely bruised in the forehead.

LONDON LETTER.

The Tuberculosis Congress.

The arrangements for the forthcoming Congress on Tuberculosis are almost complete and the meeting promises to be a very successful and important one. Over 1,200 applications for membership have been received and the number is expected to exceed 2,000. On Monday, July 22, at 3 p. m., at St. James' Hall, the Congress will be opened by H. R. H. the Duke of Cambridge at the request of the King. His Majesty has taken a great interest in the tuberculosis question and, indeed, in sanitary questions in general. When he was Prince of Wales he presided over the Society for the Prevention of Tuberculosis and it was arranged that he should preside at the opening of the Congress, but his accession to the throne has caused him to cancel the arrangement and to appoint his grand-uncle in his stead. Abroad, measures have been taken to secure a large number of foreign visitors. A German committee has been formed under the presidency of the Duke of Ratibor, and a French committee under Professor Brouardel. Amongst those enrolled are Prince d'Arenberg, Profs. Lannelongue, Proust and Nocard. Professor Calleja, president of the next International Congress in Madrid, is promoting the interests of the Congress in Spain. Profs. von Schrötter and Weichselbaum will represent Austria. Among American representatives are Profs. Osler and Janeway. Numerous adhesions have been received from Italy, Hungary, Belgium, Norway and Sweden, Holland, Switzerland, and Portugal. A reception will be held at 9 p. m., on the opening day at the Queen's Hall by the president of the Council and the executive officers of the Congress. On July 23, at 3 p. m., the second general meeting will be held at St. James' Hall, when an address will be delivered by Koch, Lord Lister in the chair. Koch will deal with the question: "Whether what has been done and what is likely to be done for the prevention of tuberculosis corresponds to the etiological conditions of the disease and how far changes with view to more thorough treatment should be instituted." Professor Brouardel will deliver an address on July 24. Receptions, garden parties, river parties, etc., will be held in connection with the Congress, which promises to be as successful from the social as the scientific standpoint. Arrangements will also be made for visits to Sanatoria and other places of interest.

Departure of the Fifth Malaria Expedition From the Liverpool School of Tropical Medicine.

The extraordinary enterprise of this recently established school is shown by the organization of five malarial expeditions. Major Ross, whose name has been rendered famous by the proof of the mosquito theory of malaria, and Dr. Turner, assistant lecturer in pathology at the University of Glasgow, have been sent out to West Africa in order to attempt the extermination of the anopheles mosquito. It is thought that the Colonial Office will send a representative to assist in the work. Mr. Chamberlain has sent a message wishing the expedition every success and intimating that he has instructed the Governor of Sierra Leone and other officials to give the expedition every assistance in their power.

Army Medical Reform.

A committee of experts has been appointed to consider a scheme of reform drawn up by the Secretary for War. It consists of the following members: Howard H. Tooth, M.D., F.R.C.P., representing St. Bartholomew's Hospital; G. H. Makins, F.R.C.S., St. Thomas's Hospital; Alfred D. Fripp, Guy's Hospital; Sir F. Treves, London Hospital; Alexander Ogston, Scotland; Lieutenant Colonel Keogh, Ireland; E. E. Perry, M.D., F.R.C.P., Senate of London University; Surgeon-General Hope, President of the Medical Board, India Office. Most of the civil practitioners have served in the South African war and therefore are peculiarly fitted for the task of remedying the defects of the army medical system.

Suicide of a Surgeon.

Considerable sensation has been produced in medical circles by the suicide of Mr. Thomas Bond, the well-known medical jurist who figured in almost every *cause celebre* in which medico-legal questions arose. He had been suffering from cancer of the prostate, which caused great pain. He took considerable morphia and was heard to say: "I am sure I shall jump out of the window or blow my brains out." Generally speaking, he was a strong-minded and courageous man. During the absence of his nurse he threw himself out of the window and fell on his head a distance of 50 feet. In 1873 he was appointed assistant surgeon to the Westminister Hospital, but it was as an expert in criminal cases, such as the trials for murder of Kate Webster, Lamson, Lefroy, and Mrs. Pearcey, that his reputation lay. He had extraordinary experiences of railway accidents, and companies often resorted to his services to protect themselves against the claims of malingerers. He was one of the best of medical witnesses. His evidence was clear and carried conviction, and having formed an opinion he adhered to it with a tenacity which no cross-examination could shake.

Report of the Committee of Inquiry of the National Hospital for the Paralyzed and Epileptic.

The circumstances leading to the appointment of this committee have been previously described in THE JOURNAL. The report which is unanimous has been presented to the governors. The witnesses heard comprised experts in hospital management, Lord Lister, Sir Wm. Broadbent, Sir Sidney Waterlow and Mr. C. S. Loch; members of the board of management; medical officers of the hospital; present and past house physicians; present and past matrons and nurses; the Secretary-Director and other officials. Of the allegations made by the medical staff the committee find that some of the most important are true; some have foundation in fact, but are exaggerated, and that others are not supported by sufficient evidence. With regard to the question of diet they find that at the beginning of last year the supplies to particular wards fell short more often than ought to have occurred. The quality of the meat, fish, eggs, and vegetables was often far from good. In a few cases the personal cleanliness of the patients did not receive sufficient care. In some wards the supply of linen was deficient. The supply of draw-sheets, which from the character of the diseases treated in the hospital are required in large quantity, was very deficient. The method of communication between the medical staff and the Board—through the Secretary-Director—has not worked well and the committee are of opinion that the direct representation of the staff on the Board would be of great and permanent benefit to the hospital and would have presented the present schism. The allegation of the Board that such representation would tend to destroy the religious and philanthropic character of the hospital, is dismissed as unfounded. The committee therefore recommend that the Board be increased by two members chosen by the medical committee from the medical staff. This change would tend to bring the hospital into line with similar institutions. The committee disapprove of the investiture of the Secretary-Director with so much power, and find that he has not used it with tact and judgment, but has exceeded his functions. They recommend the abolition of this office and the appointment of a secretary entrusted with ordinary powers who should be the chief and executive officer of the Board of Management, but be restrained from interfering with the lady superintendent or the medical staff, or that a secretary and medical superintendent should be appointed as a permanent officer, who should not only discharge the duties of secretary and house physician, but should be the responsible and resident head of the whole institution under the Board of Management. So far the prolonged and stubborn contest, which threatened to wreck one of the most useful charities in this country and one of the most famous hospitals in the world, has ended in the complete victory and vindication of the medical staff. The Secretary-Director, an able and energetic official, who has served the hospital more than thirty years, had gradually been allowed to take almost all the powers of the governing body into his own hands, and in the end attempted to over-rule the medical staff on such purely medical questions as nursing and diet. The attempt has ended as it deserved.

PARIS LETTER.

Cytodiagnosis in Inflammatory Diseases of the Nervous System.

Cytodiagnosis as a means of distinguishing certain forms of mental diseases, accompanied by inflammation from others which are neuroses, has been studied recently by Dr. Seglas and Nageotte. In 14 cases of mental disease simulating progressive general paralysis, lymphocytosis was found in 5 cases which proved to be paresis, whereas in the other 9 cases, this symptom did not exist. Dr. Joffroy, the neurologist, remarked that it was quite noticeable before the other symptoms of paresis. Drs. Dupré and Devaux communicated at the same meeting of the Medical Society eight observations of patients on whom lumbar puncture was performed. In two cases of progressive general paralysis, leucocytosis was very apparent, as indicated by Widal and his pupils. The six other cases were: One senile dementia, one organic dementia, one precocious dementia, and three cases of delirious melancholia. There was *no leucocytosis in these cases.* Dr. Widal recommended not drawing off more than 3, 4, 5, or, at the most, 6 cubic centimeters of liquid. The patients should remain in bed the rest of the day, and not raise their head from the pillow. Very fine needles should also be employed, as there is less risk of tearing the meninges.

The Use of Large Doses of Antitoxin.

Dr. Widal spoke of the method he followed out in the treatment of diphtheria. He has often seen patients come into the Maison Municipale de Sante, a species of private hospital, at the fifth or even seventh day of an attack, without having been injected. In such cases he gives doses of 60, 80, or even 100 grams of serum, and he has never seen any accidents due to the use of such large doses. In such cases paralysis may supervene, and even sudden death. It should be remembered that the serum treatment can not act when cellular lesions are already produced, and Dr. Widal therefore prefers injecting serum to a patient who does not need it than waiting too long in other cases.

Mortality of Infants in France.

Professor Budin, who has succeeded to Tarnier as professor of clinical obstetrics, made a report recently to the Academy of Medicine on the mortality of children after birth in France. According to some statistics published recently, out of 1000 deaths, there are about 167 of children less than a year old. At Lille the number is 274, 342 at Dunkerque, 414 at Nancy. This excessive mortality is due to the prevalence of gastroenteritis, which causes 385 deaths out of 2000; respiratory troubles, which bring about 147 deaths; congenital debility produces 171 cases; tuberculosis 25; contagious diseases, 50: and all other causes, 222. Professor Budin showed how these different diseases could be fought in a measure, and gave a description of various institutions not only in Paris, but at Florence, Brussels, and Montreal, where advice was given to mothers and sterilized milk was furnished. According to Drs. Balestre and Giletta, 76 per cent. of the deaths occurring during the first year could be prevented. Professor Fournier reminded the assembly that syphilis was a potent factor in the death-rate of children, half, if not more of the deaths occurring in families suffering from syphilis, being due to this disease.

Epidemic of Lockjaw.

At a meeting held by the Society of Surgery, on June 5, Dr. Reynier, surgeon of the Lariboisière Hospital, spoke of three cases of lockjaw which had been seen in his service. Six years had elapsed without his having observed a single case, when in January last he saw symptoms of it in a boy he had operated for hernia. The patient died, and four days after a woman in another ward showed signs of this disease and died the eighth day. A patient who was operated at about the same time was injected with antitoxic serum. Eight days afterwards lockjaw made its appearance, but on increasing the dose of chloral from 12 to 20 grams, the symptoms grew less alarming, and the patient recovered after three weeks. Dr. Reynier thought that it might be the catgut which had been the cause of the infection. Dr. Quénu said that he had never seen a single case of lockjaw cause an epidemic of this disease, and as for the catgut, it could be easily sterilized in alcohol at a temperature of 120° C. Dr. Delbet remarked that he remembered the case of a patient who had a mild form of lockjaw, and who was treated by injections. He rapidly grew worse and died the next day. Dr. Brun described a similar case in a child three years old. On the other hand, Dr. Bazy said that he always had injections made to patients who had bad wounds received in the street and he had only seen so far two cases of lockjaw with men who had not received this treatment. He always gave chloral in large doses in such cases.

Oxygen as a Treatment for Boils and Carbuncles.

A new treatment against boils and carbuncles has been advocated recently by Dr. Thiriar, professor of clinical surgery at Brussels. It consists in the injection of oxygen into the tumor formed by the boil. A receptacle containing oxygen under pressure may be used, and put in communication with a needle, which is inserted under the skin. One injection is found sufficient for an ordinary boil; for a carbuncle it is well to inject oxygen through the different openings. The anthrax becomes painless in a relatively short space of time, and the inflammation disappears in a few days.

Book Notices.

A Text-Book of Gynecology. Edited by Charles A. L. Reed, A.M., M.D., President of the American Medical Association (1900-1901.) Illustrated by R. J. Hopkins. Cloth. Pp. 900. Price, $5.00. New York: D. Appleton & Co. 1901.

This is a composite book—a book with many authors. It is the kind that the average book agent will insist is, and must be, good because so many good men have contributed to it. The reviewer believes that, as a rule, the opposite is true, viz., that when the responsibility is divided the result is likely to be as the meal prepared by many cooks. However, in the book before us the editor has come as near to eliminating the objections to a composite book as one could wish. While there are thirty-one contributors, a thorough editorial revision has made a uniformity of style and expression throughout that would have been impossible with such a large number of contributors had this not been made. The awkwardness, the lack of continuity of thought, and the repetition that is so common when many contributors write on allied subjects, have all been eliminated. Even the references to their own work by the different writers has been rendered into the third person. There has been a greater subdivision of labor in the preparation of this book than is usual, even in this age of collaboration. Thus we find among the contributors specialists in pathology, in neurology, in dermatology, in hygiene, etc. In the chapter on neoplasms of the uterus there are no less than eight different writers; but when it is remembered that each of these has obtained a reputation in the subject on which he writes, and that the whole has been made consecutive by the editor, all objections to this multiplicity of contributors is removed. While much of the work is of the composite nature, quite a number of the subjects are considered by individuals. Three chapters devoted to the subject of Diseases of the Female Generative Organs are written by M. L. Harris. These would make a splendid monograph on the subject, for they treat it in an exhaustive manner. The writer shows that he has a thorough knowledge of the matter, and has presented it in a most acceptable manner. Some of the subjects considered do not strictly belong to a work on gynecology—as, for instance, movable kidney, tuberculosis of the kidney, renal calculi—but they none the less add to the value of the book. The chapter on Pelvic Diseases and the Nervous Affections, by Dercum, is a valuable one. Dercum discusses the subject of neurasthenia and hysteria from the standpoint of the neurologist, but every gynecologist will endorse the assertion that no operation should be done simply to remove symptoms that are characteristic of the neuroses, but should be done for symptoms properly belonging to pelvic disease itself, and for this alone; in other words, operations should be made on surgical indications only. The three chapters on rectal diseases are out of place in a book on gynecology. The editor, in the opening paragraph, defines gynecology as "a consideration of the names, causes, prevention, diagnosis, pathology, and treatment, of diseases peculiar to women." The diseases of the rectum as they relate to the various disorders peculiar to women, are considered in their appropriate places in the book where they ought to be considered, and piles and other affections of the rectum that are common to both sexes do not come under the definition given.

While evidently it was not the design to give an elaborate description of the various operative procedures, or to take a superabundance of space with a description of minor details, yet the technic is so well presented in nearly every instance that the student will find it as helpful as though pages had to be read rather than paragraphs. The chapter on Abdominal Section is a good illustration of clear cut and easily understood descriptive writing; there is no forest of verbiage to push through, no underbrush of useless detail to get rid of. The illustrations are practically all new, being made especially for this work under the editor's direction. They are excellent and numerous. On the whole the editor is to be congratulated on the splendid work he has done in producing such an excellent up-to-date work on gynecology.

A Manual of Hygiene and Sanitation. By Seneca Egbert, A.M., M.D., Professor of Hygiene, and dean of the Medico-chirurgical College of Philadelphia. Second Edition, Enlarged and Thoroughly Revised. Illustrated with 77 Engravings. Cloth. Pp. 435. Price, $2.25. Philadelphia and New York: Lea Brothers & Co. 1900.

This second edition, occurring within two years after the appearance of the first, is itself a recommendation of any book of this class, reaching as it does, only a comparatively limited number of readers. The book is designed not merely for the medical man, but also for everyone who is interested in subjects of healthful living. Dr. Egbert has put in a convenient and readable form the main facts of hygiene and sanitation, and in the present edition has added a chapter on military hygiene as being indicated by comparatively recent events. The book as a whole has been revised, and therefore is presumed to be fully up to date. As far as we have inspected it, we find no serious discrepancies or misstatements. It is a work that can be honestly recommended not only to the medical man, but to his patients and especially to all persons who hold public offices, or even in the way of being members of boards, trustees, or otherwise having to do with matters which are in any way concerned in the question of sanitation.

Atlas and Epitome of Ophthalmoscopy and Ophthalmoscopic Diagnosis. By Prof. Dr. O. Haab, Director of the Eye Clinic in Zurich. From the Third Revised and Enlarged German Edition. Edited by Geo. E. de Schweinitz, Professor of Ophthalmology, Jefferson Medical College, Philadelphia. With 152 colored lithographic illustrations and 85 pages of text. Cloth. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co., 1901.

Professor Haab's work on ophthalmoscopy is valuable to the student and indispensable to the specialist, for nowhere else can be found such a fine pictorial collection of changes and lesions of the eye-fundus as this volume contains. The American editor has further enhanced its usefulness by annotations and additional ophthalmoscopic illustrations. Not the least pleasing feature is the low price at which this work of art has been placed in the market.

Health and Hygiene for the Household. By John Joseph Nutt, B.L., M.D., Member of the American Medical Association. Cloth. Pp. 69. Price, 50 cents. New York: The Abbey Press.

The author of this little work endeavors to acquaint the lay reader with some of the leading facts of sanitation, and its circulation ought to do much good. Such advice is what the great majority of the people need; unfortunately, however, most people will go on in their old way. We can recommend it to the public as containing a good deal of valuable and sensible advice.

Married.

Philip Le Sage, M.D., to Miss Lizzie Meers, both of Joliet, Ill., June 26.

James C. Holdsworth, M.D., to Miss Mary E. Wolf, both of Baltimore.

John M. Fouts, M.D., to Miss Flora Jones, both of Centerville, Ind., June 26.

J. Harry Ulrich, M.D., to Miss Sallie Rittenhouse, both of Baltimore, June 25.

Robert W. Markley, M.D., to Miss Myrtle Weltzier, both of Huntley, Ill., June 26.

George W. Porter, M.D., to Miss Mabel Boyer, both of Ashton, S. Dak., June 25.

Thomas J. Case, M.D., Unionville, Iowa, to Miss Dellie Hard, of Albany, Iowa, June 26.

W. F. Black, M.D., Sayreton, Ala., to Miss Elsie Kelly, of Woodlawn, Birmingham, Ala., June 21.

Arthur G. Emerson, M.D., Lewiston, Neb., to Miss Marion Riddell, of David City, Neb., June 26.

August Conrad Schuetzler, M.D., Toledo, Ohio, to Miss Lapworth, of Hokedale, Mass., June 29.

William E. H. Morse, M.D., Algona, Iowa, to Miss Carrie I. Warrick, of Davenport, Iowa, June 21.

Deaths and Obituaries.

Joseph Le Conte, M.D., College of Physicians and Surgeons, New York, 1845, died July 5, in the Yosemite Valley, where he had gone for a brief outing. He practiced at Macon, Ga., but afterwards took up the study of natural science under Agassiz. In 1851 he became professor of natural science at Oglethorpe University, in Georgia. He was employed by the confederate government as a chemist during the war. In 1869 he was appointed professor in the University of California. He had a national reputation as a teacher and writer in philosophy, history and science.

J. Augustus Ehler, M.D., Pennsylvania Medical College, Philadelphia, 1841, died, June 29, at his home in Lancaster, Pa., aged 81. He was a member of the State Medical Society, and of the American Medical Association, an organizer of the Lancaster County Medical Society, and was reputed to be the oldest practicing physician in Pennsylvania.

William E. Wright, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1866, a member of the American Medical Association, the Iowa State Medical Society and until a short time before his death, president of the Marion County Medical Society, died at his home in Knoxville, Iowa, June 19, aged 60.

Dr. Thomas P. White, University of Strasburg, Germany, 1880, died at his home in Cincinnati, June 29, aged 46, from heart disease, after an illness of some months. He had been for a number of years physician to St. Mary's Hospital; also trustee of the Public Library of Cincinnati.

James W. E. Roby, M.D., New York University, 1887, died in St. John's Hospital, Long Island City, June 25, aged 38. He began practice in the Eastern District of Brooklyn, where he became widely known.

Harry A. Merchants, M.D., Albany (N. Y.) Medical College, 1897, a member of the East Hampden and Massachusetts State Medical societies, died at his home in Monson, from blood-poisoning, June 25, aged 34.

John Beauregard Hart, M.D., University of Maryland, of Baltimore, died at the Sheppard and Enoch Pratt Hospital, near Baltimore, June 29, from apoplexy.

E. Norris Lloyd, M.D., Jefferson Medical College, Philadelphia, 1886, of Yardley, Pa., died in Philadelphia from a self-inflicted wound in the throat, June 21.

Samuel Turner, M.D., Louisville National Medical College, 1894, committed suicide by hanging, June 28, while of unsound mind by reason of the intense heat.

Philip A. Taliaferro, M.D., Jefferson Medical College, Philadelphia, 1850, of Wareneck, Va., died suddenly, while sailing, at Gloucester Court House, Va.

John G. L. Whitehead, M.D., Philadelphia College of Medicine and Surgery (now extinct), 1852, died at his home near Crosswick, N. J., June 29.

John H. Groff, M.D., University of Maryland, Baltimore, 1866, for quarter of a century a practitioner of Penngrove, N. J., died at his home in that place, June 19.

Edward P. Stuart, M.D., New York University, 1877, died at his home in Penn Yan, N. Y., June 23, from tuberculosis, after a long illness, aged 50.

Ebenezer H. DeLand, M.D., an old and respected practitioner of Worcester, Mass., died at his home in that city, June 22, from pneumonia.

Lewis M. Eastman, M.D., University of Maryland, Baltimore, 1859, died at his home in Baltimore, June 27, from paralysis, aged 64.

Edward M. Estes, M.D., University of Louisville, 1878, died at his home in McKinney, Ky., June 19, after a long illness, aged 45.

John P. Wheeler, M.D., New York University, 1843, long a resident of Hudson, N. Y., died there June 28, aged 84.

Alson J. Foster, M.D., University of Minnesota, 1901, died at the home of his parents in St. Paul, Minn., June 23.

J. Abbott Galloupe, M.D., Harvard Medical School, died suddenly in his office in Beverly, Mass., June 25, aged 29.

William R. Barker, M.D., New York University, 1882, died at Newport, Md., June 22.

Miscellany.

Woman's Medical College of Pennsylvania.

This college, now in the fifty-second year of its existence, has just issued the annual report of its maternity department, as follows: The report of the out-obstetric department for the session of 1900-1 shows the number of cases attended from May 1, 1900, to May 1, 1901, 302; the number of children born was 303. Of these, vertex presentations amounted to 285; face, 2; podalic, 10; transverse, 5. There were no maternal deaths; the fetal deaths were 20. The number of after-visits made by physicians and students was 5017. The maternal complications consisted of generally contracted pelvis, 3; oblique pelvis, due to hip-luxation, 1; rhachitic flat pelvis, 2; albuminuria, 2; placenta previa, 1; double vagina, 1; perineal and vaginal lacerations, repaired, 67. The fetal complications consisted of shoulder presentations, 2; funic prolapsus, 5; prolapse of hand, 3; Naegele's obliquity of head, 2; breech and footling presentations, 10; face presentations, 2; twins, 4; monstrosities, 2; and ruptured cord, 1. The operations were: axis traction forceps, 2; high forceps, 3; low forceps, 6; internal version, 3; manual extraction on breech or foot, 5; craniotomy, 1; decapitation in neglected transverse, 1; operation for ankyloglossia, 9; repair of perinei and vaginæ, 67. One student attended 26 cases; six students attended, each, 12 cases; two students, each, 10 cases; twelve students, each, 9 cases; eight students, each, 8 cases; three students, each, 7 cases; three students, each, 6 cases. The number of cases attended since foundation of Maternity Hospital of the College in 1888, has been 2500. The number of maternal deaths during that time was only 2. In the hospital the number of cases delivered was 110, with no maternal deaths, and 7 fetal deaths. The maternal complications of those in the hospital consisted of, placenta previa, 1; low implantation of placenta, 1; hydramnios, 2; kyphotic pelvis, 1; funnel-shaped pelvis, 2; generally contracted pelvis, 12; rhachitic, flat pelvis, 2; mitral stenosis, 1; prolapsus of hand of child, 2; and postpartum hemorrhage, 1. The following operations were attended by the students: axis-traction forceps, 2; high forceps, 8; forceps in cavity, 12; version, 2; Cesarean section, 1; Dührssen's incisions and repair, 3; episiotomy, 6; primary perineorrhaphy, 23; amputation of supernumerary thumb, 1.

Testimonials and Patent Medicines:—The manner in which at least one large patent medicine manufactory secures its recommendations were recently exposed in this city. Two young men, agents of the Peruna Medicine Company, approached Mayor Foeltzer with an offer of one dozen fine photographs for a recommendation of the wonderful curative powers of Peruna. "But," said the mayor, "I have never even seen a bottle of Peruna, let alone being lifted from the brink of the grave by using it." "That doesn't make the slightest difference," replied the agent coolly, "all you are asked to do is to sign your name as the mayor of Benton Harbor at the bottom of a sheet of paper and authorize us to write the recommendation. No one here will ever know anything about the affair as the recommendation and photo will be published in only eastern papers. It will help us to sell Peruna and will help you to get a dozen photos." The mayor read a severe lecture to the agents and then gave them two seconds to leave his presence," replied the agent cooly, "All you are asked to do is to take up with the Peruna scheme are almost murderers. Suppose, for instance, that a sick person is led to dismiss the doctors and to feed on Peruna by these fake recommendations, and then dies. Wouldn't it come pretty close to murder—murder for a dozen photographs." The Peruna agents succeeded, nevertheless, in placing a great number of photographs in both St. Joseph and Benton Harbor. In St. Joseph recommendations were secured from some of the highest city authorities and most reputable citizens. These will be published in hundreds of newspapers in the eastern states and will lead perhaps thousands of sufferers to pay their good money for a worthless medicine. Worthless, because it is presumed that an honest medicine would be boomed exclusively by its merits.—*The Evening News*, Benton Harbor, Mich., July 6, 1901.

Dentists for the English Army.—The British war office has, according to *The Lancet*, recently been asked to send to the army in South Africa four dentists, with the view to prevent the invaliding of the men by reason of "bad teeth." The authorities have complied and have applied to the British Dental Association for advice as to instruments, furniture, etc. The medical officers of the navy are now specially trained in dentistry; moreover, a complete set of dental instruments is supplied to each ship as part of the new outfit of surgical instruments.

German School Reform Congress.—The second annual gathering in Germany of persons interested in the hygienic evolution of schools, met at Wiesbaden, May 31. Resolutions were adopted urging the appointment of medical inspectors for all institutions of learning, from the lowest to the highest. The substitution of the Latin handwriting for German script was almost unanimously advocated. We mention gratefully, by the way, that our German medical exchanges are always printed in the Latin letters, that is the same as used in America, France, England, etc.

Danger in Nursing Bottles.—Physicians do not need to be told that unclean nursing-bottles are a menace to the lives of babes—but the mothers do. It is astonishing how many mothers are not only careless but actually ignorant of this danger, and it is only by repeated warnings that they are made to realize its importance. Thousands of infants are carried off every summer from this cause that might easily be saved by proper precautions on the mother's part.

International Leper Sanitarium.—The *Gazetta degli Ospedali* states that Spain is strenuously objecting to the choice of an island off Tarifa as the site of the proposed international leprosorium, fearing contagion of her possessions in Africa. Dr. Ovilo and Lieut. Castela have been delegated to present the matter at the approaching meeting of the international committee at Tangiers.

The German Committee for the Study of Cancer held a meeting recently which was addressed by Professor Schuetz on the subject of carcinoma in animals. He stated that cancer is rare in horses, but on the other hand, it frequently occurs in dogs. The external integuments are usually affected.

Professor Mantegazza's Fortieth Professional Anniversary.—The 30th anniversary of the founding of the Florence Anthropologic Society was celebrated in connection with Mantegazza's jubilee. It is announced that an anthropologic laboratory is to be founded in his honor. Retzius brought a greeting to him from the Swedish Society, and Virchow represented his Society.

A Central Station for Testing New Medicines is to be organized in Germany in connection with the National Public Health Department. The necessity of such an institution is shown by the fact that 126 new medicines were put on the market in 1899-1900.

The Spanish Authorities are putting up a memorial tablet on the house occupied by the illustrious anatomist, R. Martinez Molina, at Madrid. In our Spanish exchanges he is called the "Perla de San Carlos."

Chair of Oto-Laryngology at Rostock.—The University of Rostock is the first German medical faculty to have a regular chair for this specialty. Professor Koerner is the first incumbent.

Professor Piero Giacosa, of Turin, has been chosen president of the section of the history of medicine in the International Congress of History to be held at Rome this fall.

Association News.

THE ST. PAUL MEETING AS VIEWED BY OUR CONFRERES.

From the Columbus Medical Journal, June.

The St. Paul meeting of the American Medical Association has been pronounced by those in attendance as one of the best in the history of this great organization. The registration was almost as large as it was at the Atlantic City meeting last year, while the Section attendance was better.

The papers were, "in almost every instance above the average in scientific interest and practical value." . . . The large attendance at the Sections, and extended discussions which were full of interest, indicate that the members were making no holiday out of the sessions. The able and stimulating address of President Dr. C. A. L. Reed, who extended greetings and invoked upon the deliberations "the spirit of liberty, courage, progress, and truth," set the pace in high thinking and earnest inquiry which characterized the meeting throughout.

The presentation and unveiling of a portrait of the founder of the Association, Dr. Nathan S. Davis, was a handsome and timely recognition of the services of this distinguished leader, who, in the language of Dr. Pennington, has perhaps done more than any other individual in promoting the efficient social organization of the medical profession throughout the United States, and in elevating the standard of medical education. This ceremony led to the appointment of a committee to secure, without expense, the portraits of past presidents of the Association. The adoption of the revised constitution and by-laws assures an effectual reorganization which will bring the state societies into more vital relations with the Association, and, by the elimination of the general morning meetings, after the first day, will give more time for Section work. The limitation of the number of papers will insure more careful preparation, and more deliberate consideration of those on the program. The completeness of arrangements reflected credit upon the local profession, and the officers of the Association, while the hospitality of the twin cities of the West won the hearts of every visitor. The first meeting of the century has revealed new phases of medical science, full of promise, and under a new constitution initiated a new era of fraternal organization.

From the Southern Practitioner, July 1.

Although the meeting at Atlantic City was perhaps larger than that at St. Paul, it had but little advantage in point of numbers; and the great change in the working methods of the organization make the last meeting notably the most important in its history. While the character of the organization is not changed, the very important change made in the future as pertains to "business," as it may come before the Association, is not only a marked feature, but one of the very greatest importance, and one that we confidently believe will redound to great good. . . . Outside the possibility of greater advantages of transacting its business properly, a longer time is afforded for the scientific work of the Association. Farther, it foreshadows, or should do so, a complete reorganization of State organizations, and no time is more suitable than the present; and we most sincerely hope to witness, within the immediate future, the reorganization of all along similar lines. Possibly local environments or customs may require some slight variations, but the general characteristics of the National, should pervade all State and Territorial Societies.

The addresses of the President, together with that on Medicine, Surgery and State Medicine, as well as the scientific work in all the Sections, so far as we can learn, compare favorably with any preceding meeting. The exhibits were well up with former meetings, and the hotel facilities were satisfactory. As for the social entertainments afforded, both general and private, as an experienced delegate, one who has been quite a regular attendant for a number of years expressed himself, "St. Paul just spread herself, and Minneapolis helped her." The election of Dr. John A. Wyeth, of New York, as President, is a fitting recognition of his abilities as a student of science, a faithful and careful worker, an eminent surgeon, and a most worthy member of his profession, and courteous gentleman. The selection of the other officers we believe will give as much satisfaction as is possible, as will also the selection of Saratoga as the next place of meeting.

The Journal of the Association is in a most prosperous condition, . . . and is rapidly becoming just what it should, the exponent of American medical opinion and thought. Yes, truly, an organ of the American medical profession with influence and weight.

From Medical Fortnightly, June 25.

It was a great meeting in every sense of the word. The attendance was large, over 2000 physicians were registered, while fully 500 more were present as lookers on. The weather was not perfect, but in spite of the rain, it was agreeable and the elements did not interfere with the proceedings of the society. St. Paul looked its best, the people did their best, and the physicians went one better, and were tireless in their desire to make the meeting a memorable one to all who came. As a result St. Paul will always figure in the history of the society. The greatest event of the meeting was the adoption of the plan of reorganization, which was unanimously accepted and became a law at this meeting.

The society is now upon a solid working basis, with stable features and powers which will be sure to yield results. The scientific work of this meeting was of a superior order, the various sections being full and of especial service to all who attended. The number of papers being less than at former meetings, more time was given to discussion. Discussion is the life of a medical meeting; this was proven true at St. Paul. Another feature, which is commendable, is that of varied symposia —a symposium with discussion on a certain subject is carefully planned and the subject exhaustively treated. The result is all that is new, all that is worthy and helpful upon a certain subject is presented and thoroughly discussed.

From Medicine, July.

The St. Paul meeting of the Association has passed into history, and will be long looked upon as one of the most successful and perhaps epoch-making in the progress of the Association.

The adoption of the report on reorganization was inevitable. A very small minority opposed it, but the concensus of opinion, being so overwhelmingly in its favor, meant that it would be promptly carried when it came to a vote. It was claimed on the floor of the convention that the proposed House of Delegates was creating an undemocratic star chamber to arbitrarily govern the Association. This suggestion came from that small coterie of individuals who, in the past, have largely attended to the business of the convention and whose occupation under the new order of things will be somewhat restricted. The creation of the House of Delegates is, in effect, enlarging the governing body and giving it a thoroughly representative character. It will relieve the general sessions of all business details, and, while they may be less picturesque, they will be more orderly.

From the St. Paul Medical Journal, July.

It was with mingled feelings of regret and relief that we witnessed the adjournment of the 52d annual meeting of the American Medical Association, which will meet next year in Saratoga. The meeting was a large one, the actual registration being eighteen hundred and ten, and there were not far from twenty-five hundred in attendance, and the body of delegates was an unusually representative one. We shall make no attempt to report the meeting in detail, as we assume that all of our readers have access to one or more of the weekly journals in which this is done much more accurately than we could do it if we attempted to. The most important event of the meeting, indeed we believe the most important event in the history of the Association, was the adoption in a modified form of the report of the Committee on Organization. We hope that every member of the Association will read carefully the plan of reorganization as it was finally adopted, and that every state and county medical society in the country will adopt the recommendations concerning membership there suggested. This matter was discussed by Dr. Wm. Davis in his address, as President of the Minnesota State Medical Society, and the Society appointed a committee to consider the matter in all its details and to report at the next annual meeting. We shall have frequent occasion to refer to this matter, and at this time we will simply say that the plan meets with our hearty approval and that we believe that it will accomplish a vast amount of good for the Association in many ways. It will, among other things, purify the politics of the Association; it cannot do away with politics, for in an association of this kind some politics are unavoidable, but with the elective power in the House of Delegates, it is not at all likely that organized cliques will come to the annual meetings with their candidates for the various offices determined upon and with a carefully arranged plan of campaign for their election. Dr. Reed was almost ideal as a presiding officer, firm, dignified, and with a perfect knowledge of parliamentary law, and his presidential address, as might be expected by those familiar with his gifted pen, was a broad, scholarly and thoughtful document, containing many helpful suggestions concerning the policy and the possibilities of the Association. It should be carefully read by those who were denied the privilege of listening to its eloquent delivery.

The Section meetings were well attended and a very large number of valuable papers were read and discussed. The Pathologic Exhibit excited much interest and a great many important subjects in pathology were represented by carefully prepared specimens and series of preparations, photographs and microscopic slides. The series of wax models representing various stages of smallpox prepared by Mr. Dahlgren, of Minneapolis, for the Pathological Laboratory of the University of Minnesota attracted much attention and was highly commended. The General Exhibits were interesting, well conducted, largely attended and satisfactory both to the exhibitors and the local committee. The hotel arrangements were admirable and we heard no complaints of uncomfortable accommodations or overcrowding. Concerning the entertainments and the social features of the meeting it is perhaps not becoming for us to speak, but we were much gratified to hear on all sides such cordial and spontaneous expressions of appreciation from our guests and we feel sure that everybody had a good time.

New Members.

The following is a list of new members of the American Medical Association for June, 1901:

ALABAMA.

Zimmerman, Albert S., Killen.
Goggans, J. A., Alexander City.
Watkins, I. L., Montgomery.

ARIZONA.

Craig, R. W., Phoenix.

ARKANSAS.

Goree, J. L., Pine Bluff.

CALIFORNIA.

Bullard, F. D., Los Angeles.
Fales, Louis Henry, San Francisco.
Bruner, Francis Marion, Santa Ana.
Caglieri, G. E., San Francisco.
Ransom, S. A., *Angel Island.*
LeFevre, Joseph P., San Francisco.

CONNECTICUT.

Goodenough, Edw. W., Waterbury.
Hammond, H. L., Killingly.
Kellogg, K. E., New Britain.

COLORADO.

Friedmann, A. C. H., Colorado Springs.
Phillips, C. W., Rocky Ford.

DISTRICT OF COLUMBIA.

Fisher, W. N., Washington.
Wertenbaker, C. P., Washington.

GEORGIA.

Chason, J. D., Bainbridge.
Battey, Wm. W., Augusta.

INDIANA.

Culp, L. L., Ft. Wayne.
Wardner, Horace, Laporte.
Cole, A. M., Indianapolis.

ILLINOIS.

Petersmeyer, Wm., Ashton.
Rutledge, J. A., Elgin.
Brewer, E. J., Ashton.
Rice, Delia N., Galesburg.
Chapin, H. A., White Hall.
Halberg, C. S. N., Chicago.
Johnson, C. W., Chicago.
Swan, C. F., Chicago.
Stewart, W. T., Chicago.
Andrews, E. W., Chicago.
Goodsmith, H. M., Chicago.
McIntyre, C. J., Chicago.
Martin, F. H., Chicago.
Sanford, W. C., Chicago.
Sandberg, K. F. M., Chicago.
Stevenson, A. F., Chicago.
Stewart, H. J., Chicago.
Webster, E. M., Chicago.
James, R. L., Blue Island.
Lillie, C. W., East St. Louis.
McGowen, T. J., Palestine.
McLaughlin, W. K., Jacksonville.
Norton, F. D., Columbus.
Peyton, D. C., Jeffersonville.
Sourwine, J. D., Brazil.

IOWA.

Patterson, W. E., Greene.
Field, Geo. Alfred, Callender.
Sowles, E. E., LuVerne.
Pattison, I., Oelwein.
Ryan, G. N., Des Moines.
Saunders, C. J., Ft. Dodge.
Warren, J. N., Sioux City.
Smith, Frank S., Nevada.
Bachman, E. W. Estherville.
Chase, C. S., Waterloo.
Deering, A. B., Boone.
Dean, F. W., Council Bluffs.
Dennis, E. G., Charles City.
Downing, W. L., Moulton.
Farnsworth, H. S., Clinton.
Fuller, Z., Sac City.
Graham, J. C., La Porte City.
Hanna, J. W., Winfield.
Harding, L. W., Salon.
McLaughlin, A. J., Sioux City.
McLean, J. W., Fayette.
Pond, A. M., Webster City.
Rawls, J. A., Creston.
Shellito, A. G., Independence.
Smith, E., Aurora.
Stevens, G. M., Decorah.
Stockman, G. C., Mason City.
Vest, F. E., Montezuma.
Herrick, S. J., Everest.
Waterman, J. C., Council Bluffs.

KANSAS.

Elmore, R. B., Osburg.
Farney, Haydee M., Mound City.
Parker, John B., Hill City.
Hunter, Randall R., Fulton.
Harkey, Wm. Cathey, Gardner.

KENTUCKY.

Smith, J. W., Clinton,
Schachner, Aug., Louisville.
Linn, C. H., Kuttawa.
Powell, W. D., Harrodsburg.
Aud, C. Z., Cecilian.
Frank, L., Louisville.
Green, J. T., Leitchfield.
McCormick, A. T., Bowling Green.

MASSACHUSETTS.

Harding, Walter A., Everett.
Gay, Wm. Fred'k, Boston.
Frame, Jos., Rockland.
Hatch, Leonard F., Lynn.
Leonard, Jr., E., Melrose.

MAINE.

Foster, B. B., Portland.

MICHIGAN.

McHench, W. J., Brighton.
Layton, Matthew A., Woodmere.
Alway, Geo. H., Gaines.
Shaw, Nenian T., Birmingham.
Seeley, Oscar F., Climax.
Warthin, Alfred S., Ann Arbor.
Ballard, W. R., Saginaw.
Bliss, J. W., Saginaw.
Godfrey, W. L., Battle Creek.
Kellogg, P. S., Battle Creek.
McLurg, J., Bay City.
Stewart, C. E., Battle Creek.
Tupper, V. L., Bay City.
West, W. K., Calumet.
Shurly, B. R., Detroit.

MINNESOTA.

Barck, G. W., Albert Lea.
Nichols, G. W., Milaca.
Freeman, J. P., Emmons.
Wing, I. C. J., Clinton.
Bouman, Hermann, Torah.
Hawkins, V. J., St. Paul.
Smith, P. Albert, Faribault.
Phillips, J. R., Northfield.
Burgan, Jas Homer, Tracy.
Mann, Arthur T., Minneapolis.
Hesselgrave, S. S., St. Paul.
Avery, J. F., Aitkin.
Wood, W. S., Geneva.
Johnson, Osa, St. Paul.
Nippert, H. T., St. Paul.
Behrens, B. M., Minneapolis.
Bjelland, A. O., Mankato.
Holbrook, J. S., Mankato.
Johnson, J. S., St. Paul.
Landenberger, John, New Prague.
McKinnon, Malcolm, Fosston.
Miller, A. W., St. Paul.
Whitcomb, E. H., St. Paul.
Morley, Wm. B., St. Paul.
Sherwood, Geo. S., Kimball.
Vittum, W. H., St. Paul.
Camp, J. L., Brainerd.
Dimmitt, F. W., Red Wing.
Jacoby, Wm., Wells.
Allen, A. W., Austin.
Adsit, A. M., Hastings.
Anderson, C. A., Rush City.
Arzt, C. P., St. Paul.
Bachman, C. E., Evansville.
Barton, G. C., Minneapolis.
Bean, C. E., St. Paul.
Bole, R. S. St. Paul.
Boot, G. W., Lamberton.
Boyd, C. A., Lewiston.
Braden, A. J., Duluth.
Bray, C. W., Biwabik.
Buckley, E. W., St. Paul.
Button, A. J., Hammond.
Burton, C. N., Elinore.
Cremer, M. H., Mazeppa.
Cox, A. J., Tyler.
Dodge, F. A., Le Sueur.
Dodge, W. M., Farmington.
Dunn, J. B., St. Cloud.
Ely, C. B., Rochester.
Franchere, F. E., St. James.
Freeman, W. W., Grand Meadow
Fritsche, L. A., New Ulm.
Frost, E. H., Wilmar.
Gallagher, J. W. S., Winona.
Hansen, M., Hendrum.
Lichtenstein, H., Winona.
McKean, J., Montgomery.
Mayland, M. L., Faribault.
Mikkelsen, M., Wells.
O'Hara, J. J., Alma City.
Peters, R. M., Minneapolis.
Plondke, F. J., St. Paul.
Pritchard, D. B., Winona.
Randall, B. M., Graceville.
Renz, G. A., St. Paul.
Roberts, T. S., Minneapolis.
Rood, D. C., Hibbing.
Rose, F. M., Faribault.
Schoch, J. L., New Ulm.
Simpson, J. D., Minneapolis.
Schofield, C. L., Benson.
Schoonmaker, E. C., Perham.
Slocumb, J. A., Plainview.
Stoner, R. R., Winthrop.
Stover, E. E., Bigelow.
Trace, O. C., Little Falls.
Van Beeck, H. G. C., Hastings.
Waltam, G. S., Warren.
Watson, T. R., Zumbro Falls.
Williams, John, Lake Crystal.
Wood, E. S., St. Paul.
Ritchie, P., Ramsey.

MISSISSIPPI.

Ballard, J. C., Natchez.
Harris, T. A., Rosedale.

MISSOURI.

[illegible] A., Kirksville.
[illegible]
Sawtell, J. E., Kansas City.

Wiley, F. S., Fond du Lac.

Report on the Pathologic Exhibit of the American Medical Association at the St. Paul Meeting Held June 4 to 7, 1901.

FRANK B. WYNN, CHAIRMAN,

INDIANAPOLIS.

Many have borne appreciative testimony to the success of the first Pathologic Exhibit of the Association, inaugurated at Atlantic City a year ago. It was a wholesome digression from the monotony of commercial exhibits and appealed at once to those striving for the higher ideals in medicine. The pathologist, expert clinician and general practitioner alike found it interesting, instructive and useful. Considering the ethical and scientific spirit of the Association, official approval of the movement was a result anticipated. An appropriation was made commensurate with the importance of the work, which was to be under the supervision of the Section on Pathology and Bacteriology.

Profiting by the experience of a year ago, it was hoped for the St. Paul meeting to secure a better balanced exhibit, both in the scope and character of material presented. The difficulties in the attainment of this end were, first, to secure the promise of exhibits, and secondly, to ascertain from prospective exhibitors a list of what it was designed to contribute. In this way it was sought to obtain an approximate estimate of the quantity and character of available material. Thus, would unnecessary duplication of specimens be avoided, and the exhibit built up at weak points, giving it symmetry. In the very nature of things this was an arduous undertaking, both on the part of the Committee and those who signified a willingness to contribute. In the main the hopes and desires of the Committee have been realized. When it is remembered that the large labor necessary in the preparation and presentation of the exhibit was performed by exhibitors gratuitously, one can but marvel at the results attained. What stronger proof could be given of the unselfishness of the true scientific spirit? A corps of over fifty scientific workers, many of them eminent in the field of pathology, labored faithfully for this enterprise at home, and at the St. Paul meeting subordinated pleasure to the successful demonstration of the Pathologic Exhibit, making of it a great common school of practical pathology, for the rank and file of the profession. They merit and have won the grateful thanks and unstinted praise of the whole Association.

Although the Pathologic Exhibit is under the direction of the Section on Pathology and Physiology, it is a feature of the Association to which all Sections are related. Next to the place where the general sessions are held, the Pathologic Exhibit rooms should be the most important common meeting-place for the members of all Sections. It is, therefore, the duty of the Committee of Arrangements each year, to provide for the Pathologic Exhibit, ample space, conveniently located, well lighted, and separate and distinct from the commercial exhibits. The local committee on Pathologic Exhibit deserves thanks for securing the best available quarters at St. Paul. Unfortunately the room was not convenient of access. Consequently, the attendance at the exhibit was not what its excellence warranted.

In the summary which follows, the merest reference only is possible to exhibitors and their collections. Inadequate as the report of necessity is, it will give the reader a general idea of the great work accomplished in this practical scientific department of the Association.

A.—SOCIETIES.

Cincinnati Academy of Medicine: H. J. Whitacre.

Miscellaneous specimens	50

This well-known medical organization did credit to itself and the Queen City by sending to the exhibit this excellent collection. Particularly noteworthy was a series of specimens illustrative of prostatic hypertrophy.

Indiana State Medical Society: Frank B. Wynn, Indianapolis.

Photomicrographs of malarial blood, etc	50
Photographs illustrative of different types of feeble-minded	25
Series of photographs illustrative of different types of criminals	42
Gross specimens	110
Total	227

Especially interesting was the group of photomicrographs of malarial blood and bacteria by C. S. Bond; also the series of photographs representing different types of criminals, by A. L. Spinning. Among the gross specimens was shown a group of livers illustrating beautifully and typically alcoholic, syphilitic and biliary cirrhosis. There was also a fine series of brains showing cerebral hemorrhage. This Society participated in the exhibit last year and enjoys the distinction of being the pioneer in this line of society work.

Kansas State Medical Society: Geo. A. Boyd, Baldwin.

Miscellaneous collection of gross specimens	30

Most interesting and instructive in this exhibit was a collection of mosquitoes from all parts of the world, mapped to show their relationship to malaria.

Wisconsin State Medical Society: H. V. Würdemann and Gustav A. Kletzesch, Milwaukee.

Collection of eye specimens	40

This extraordinary collection of eye specimens, beautifully mounted in glycerin jelly, gave a very comprehensive view of gross pathologic conditions of the organ.

B.—COLLEGES.

Chicago Policlinic: Maximilian Herzog.

Gross specimens	30

Very interesting in this collection was a series of tubal pregnancies and several specimens of myoma complicating pregnancy.

College of Physicians and Surgeons, Chicago: W. A. Evans, W. T. Eckley and C. E. Coates.

SEMI-MOIST AND DRY SPECIMENS.

Nasal fossa and accessory sinuses	20
Antrum of Highmore	12
Dural sinuses	12
Of male and female pelves	5
Pott's fracture, tubercular spine, etc	5
Joints	12
Male urethral	6
Brain and spinal cord	7
Pathologic skiagraphs	65
Photomicrographs	36
Miscellaneous	5

WET SPECIMENS.

Tuberculosis	20
Carcinoma	10
Gangrene	6
Uterus and ovary	16
Miscellaneous	8
Total	245

This very large and beautiful collection consisted of anatomic as well as pathologic specimens and was especially noteworthy for its superior average excellence. The semi-moist specimens exhibited outside of containers, afforded great advantages for close inspection.

McGill University, Montreal, Canada: J. G. Adami.

Miscellaneous specimens	11

Prof. Adami was not able to be present in person, but evidenced his interest in the exhibit by sending this choice collection. Very striking was the group of cerebral aneurysms.

Hamlin University, Medical Department, Minneapolis: J. F. Corbett.

Gross, dry, bone specimens	75

This beautifully mounted collection of bone specimens represented a wide range of pathologic conditions.

Medico-Chirurgical College, Philadelphia: Joseph McFarland,

Skiagraphs	26
Microscopic demonstrations	25
Total	51

The striking feature of this exhibit consisted of a series of microscopic specimens showing beautifully all the various neoplasms and other important pathologic conditions found in the mammary gland.

Northwestern University Medical School, Chicago: G. Fütterer and F. Robert Zeit.

This remarkable collection consisted of tumors grouped anatomically as follows:

A. Endothelioma of humerus with extensive metastases	6
B. Carcinoma of uterus	9
C. Primary carcinoma causing implantation in other organs	4
D. Carcinoma with cells performing physiologic function like organ where found	1
E. Carcinoma of breast with many metastases	4
F. Carcinoma of gastro-intestinal tract, particularly of stomach in reference to gastric ulcer	12
G. Tumors of the mamma	5
H. Cysts of ovaries	7
I. Miscellaneous	17
Photographs accompanying the foregoing	50
Total	115

These were all Kaiserling preparations, mounted in unique oak frames with glass centers. getting rid of the refractive distortions of round jars. The entire group was instructive alike to the pathologist and practitioner.

Wisconsin College of Physicians and Surgeons, Milwaukee.

Miscellaneous gross specimens	17

Some of these were very excellent specimens.

Rush Medical College, Chicago: Ludvig Hektoen and H. G. Wells.

Jar specimens, miscellaneous	35
Bone specimens, dry	6
Group of eye specimens mounted in glycerin jelly	12
Photographs	14
Cultures of blastomycetic dermatitis	20
Books illustrating laboratory training	14
Total	101

The students' note-books which were exhibited contained many original drawings of exceptional merit, which bore eloquent testimony to the superior laboratory training received. The jar specimens were all rare. Almost without exception, they were accompanied by published reports.

University of Minnesota, Minneapolis: F. F. Wesbrook, L. B. Wilson and S. M. White.

Sets of cultures of bacteria showing method of preserving cultures for purposes of demonstration	26
Colored wax models of smallpox, chicken-pox, pemphigus, etc., made by B. E. Dahlgren from plaster impressions taken by G. D. Haggard	40
Jar preparations—miscellaneous	149
Dry bone and other specimens	18
Photographs	20
Large water colors, illustrating classification of bacillus diphtheriæ	21
Total	274

Most striking in this large and well-arranged exhibit was the beautiful set of wax models referred to above. The plan of preserving cultures for purposes of demonstration is unique, artistic and practical. The excellence of this collection was made patent by the constant presence of someone to demonstrate the specimens.

C.—HOSPITALS, MUSEUMS, ETC.

Central Indiana Hospital for Insane: George F. Edenharter and William Charles White.

Photographs illustrating different types of insanity	62
Photographs of Pathological Building and equipment of hospital	26
Gross specimens	12
Total	100

The photographs of the insane were especially fine. Noteworthy among the gross specimens was one of biliary cirrhosis *arising from obstruction of the common duct by a stone.*

Iowa Hospital for Insane, Independence: Gershom H. Hill and Albert M. Barrett.

Miscellaneous gross specimens	30

These were all Kaiserling preparations and accompanied by carefully prepared data, bearing excellent testimony to the pathologic work being done in the institution.

Government Hospital for Insane, Washington, D. C.: A. B. Richardson and I. W. Blackburn.

Miscellaneous gross specimens	40

This institution contributed very generously toward the success of the Atlantic City Exhibit. Although neither representative was able to be present this year, their good will toward the movement was shown in this excellent collection of gross specimens contributed. Very beautiful were those of aneurysm of the heart, hepatic, cirrhosis and prostatic hypertrophy.

Lakeside Hospital, Cleveland: W. T. Howard, Jr.

Miscellaneous gross specimens	25

This institution was very creditably represented both this and last year. Rare and instructive were the neoplasms as follows: Carcinoma with tuberculosis of cecum; primary carcinoma with cirrhosis of liver; angio-sarcoma of humerus; primary muscle cell sarcoma of uterine wall; sarcoma of both suprarenal bodies; and primary sarcoma of stomach.

St. Luke's Hospital, Richmond, Va.: Stuart McGuire.

Stone in the bladder with foreign bodies as neuclei	5

These stones were removed from the female bladder. Three were formed on hair-pins: another about a broken fragment of gum catheter, and the fifth upon a segment of a silver catheter.

St. Mary's Hospital, Rochester, Minn.: Drs. Mayo.

Miscellaneous gross collection	27

The distinctive feature of this collection was a series of pathologic appendices showing: 1. Acute appendicitis, 6 to 36 hours after primary attack. 2. Showing abscess, gangrene and foreign bodies. operation 3 to 12 hours after first attack. 3. Chronic form, operation between attacks. 4. Chronic obliterating appendicitis.

St. Peter Hospital for Insane: H. D. Valin.

Pathologic brains, dry	12
Wet specimens	8
Casts of brains	10
Photomicrographs	37
Miscellaneous	68
Total	135

This entire collection gave ample evidence of excellent work being done in this institution in the field of neuropathology.

Department of Public Health, Chicago.

Photographs of smallpox and chicken-pox	50

This was a most excellent series of photographs.

U. S. Army Medical Museum, Washington, D. C.: Col. Calvin DeWitt and Capt. A. E. Bradley.

Radiographs of gunshot fractures received by soldiers in the Spanish-American war	24
Fractures received by soldiers in the war of 1861-65, of interest by way of comparison with the radiographs. The varying effect of the different type of missile was well shown	25

Intestinal lesions of typhoid fever and dysentery	17
Finely mounted series of dental deformities	35
Plaster casts of Peruvian skulls, showing prehistoric trephining. Some of these skulls presented evidence of healing after operation	19
Total	120

This very fine collection, sent from the great Army Medical Museum, is evidence of the good will borne the Pathologic Exhibit by Surgeon General Sternberg and his colleagues.

U. S. Bureau of Animal Industry, Washington, D.C.: D. E. Salmon.

Tuberculosis in meat, specimens	50

Those who attended the Atlantic City meeting will recall the extraordinary demonstration of diseased meats which Dr. Salmon made in the Pathologic Exhibit, comprehending all the gross pathologic conditions found in Government meat inspection. For this year's Exhibit he again presented cold-storage specimens, limiting them, however, to tuberculosis in animals. This typical group, eminently interesting and instructive in itself, was rendered doubly so by its proximity to the group showing tuberculosis in the human being.

INDIVIDUALS CONTRIBUTING COLLECTIONS.

Emil Amberg, Detroit.

This was a collection of dry-bone specimens which proved extremely interesting to otologists. They were grouped as follows:

1. Series showing variation in position of lateral sinus (temporal bones)	20
2. Specimens with abnormally developed styloid process (temporal bones)	20
3. Specimens showing development of styloid process at different ages	29
4. Specimens showing topographic anatomy of ear	21
5. Other specimens	4
Total	94

Edward Boeckmann, St. Paul.

Photographs of lepers	14

This was an exceptionally fine series of photographs, representing the different varieties and stages of the disease.

Frederic S. Dennis, New York.

Gross specimens	100

Dr. Dennis exhibited a series of sarcomata and carcinomata involving the bones and glands. They were presented in connection with a paper read before the Section on Surgery and Anatomy, on "Treatment of Malignant Disease by Surgical Operation." The specimens were from his tabulated cases in which no recurrence has taken place.

James Nevin Hyde and Frank Hugh Montgomery, Chicago.

Photographs of blastomycetic dermatitis	53
Cultures of blastomycetic dermatitis	20
Total	73

This beautiful series of photographs was highly appreciated by all dermatologists as well as many others interested in this rare skin affection upon which these gentlemen are eminent authorities.

Leo Loeb, Chicago.

Specimens	20

This was a most excellent demonstration of research and experimental work, a feature of the Pathologic Exhibit which the Committee has been anxious to build up. The bodies of ten rats were exhibited, showing tumors in a series of succeeding transplantations of sarcoma of the thyroid in a rat. Drawings from microscopic sections accompanied the gross specimens.

Charles Lester Leonard.

Beautiful series of skiagraphs, showing renal and urethral calculi	10
Total number of specimens constituting the Pathologic exhibit	2130

Societies.

Chicago Electro-Medical Society.—This society has been organized with Dr. Shobal V. Clevenger, president, and Dr. Gordon G. Burdick, secretary.

Northwestern University Medical School Alumni Association.—At the annual meeting of this association, Dr. William A. Mann, Chicago, was elected president, and Dr. Henry B. Hemenway, Evanston, secretary.

Panhandle (of Texas) Medical Society.—The seventh quarterly meeting of this society will be held at Amarillo, July 16 and 17, under the presidency of Dr. David R. Fey of that place.

Practitioners' Club (Jersey City, N. J.).—At the fourth annual meeting and dinner of this club, June 11, Dr. Gordon K. Dickinson, Jersey City, was elected president; Dr. Charles A. Gilchrist, Hoboken, vice-president, and Dr. George W. Shera, Jersey City, secretary and treasurer.

New York State Medical Association.—Third District Branch.—The annual meeting of this branch of the State Association was held in Ithaca, June 13 and 14. Dr. Elias Lester, Seneca Falls, was elected president; Dr. Bernard S. Moore, Syracuse, secretary, and Dr. Chauncey P. Biggs, Ithaca, treasurer.

Ulster County (N. Y.) Medical Association.—The Ulster County branch of the New York State Medical Association was organized at Kingston, June 20, with the following officers: Dr. Fred Huehne, Rondout, president; Dr. James L. Preston, Kingston, vice-president; Dr. Alice Devine, Ellenville, secretary, and Dr. Alexander A. Stern, Rondout, treasurer.

Union County (Ohio) Medical Association.—The physicians of Union County met at Marysville, June 11, and organized an association with the following officers: Dr. David W. Henderson, president; Dr. Charles McCune, of Unionville, and Alexander Smith, of Pottersburg, vice-presidents, and Dr. Stanley J. Bowen, of Claiborne, secretary and treasurer.

Northern Aroostook (Maine) Medical and Surgical Society.—The annual meeting of this society was held at Caribou, June 11. The following officers were elected: Dr. Herbert F. Kalloch, Fort Fairfield, president; Drs. Charles E. Dow, of Mapleton, and E. H. Doble, of Presque Isle, vice-presidents; Dr. Jefferson F. Cary, Caribou, treasurer, and Dr. W. G. Chamberlain, Fort Fairfield, secretary. The next meeting will be held in September at Presque Isle.

Washington State Medical Society.—The twelfth annual meeting of this society was held at Seattle, June 18, 19 and 20. A committee was appointed to devise a common form of constitution for the various county medical societies throughout the state. The election of officers resulted as follows: Dr. John W. Bean, Ellensburg, president; Drs. Henry B. Luhn, of Spokane, and Frantz H. Coe, of Seattle, vice-presidents; Dr. James B. Eagleson, Seattle, treasurer, and Dr. Arthur H. Coe, Spokane, secretary. Tacoma was selected as the meeting-place for 1902.

New Jersey State Medical Society.—The 135th annual meeting of this society was held at Deal Beach, June 25-27. Acting President Dr. John D. McGill, Jersey City, in the chair. The following officers were elected: Dr. John D. McGill, Jersey City, president; Drs. E. L. B. Godfrey, of Camden, Henry Mitchell, of Asbury Park, and Addison W. Taylor, of Beverly, vice-presidents; Dr. Ellis W. Hedges, Plainfield, corresponding secretary; Dr. William J. Chandler, South Orange, recording secretary, and Dr. Archibald Mercer, Newark, treasurer. The next meeting will be held at Atlantic City.

Wisconsin State Medical Societies.—A joint meeting of the Wisconsin State Medical Society, Wisconsin State Eclectic Medical Society and Homeopathic Medical Society of the State of Wisconsin was held in Waukesha, June 26. Dr. William H. Washburn, Milwaukee, representing the regular school, delivered an address on "The State Control of the Practice of Medicine;" Dr. J. V. Stevens, Jefferson, representing the eclectic school, spoke on "The Sanitation and Public Control of Charitable Institutions," and Dr. Quincy O. Sutherland, representing the homeopathic school, addressed the convention on "The National Control of the Practice of Medicine."

Colorado State Medical Society.—The annual meeting of this society was held June 18, 19 and 20, at Denver, Dr. William P. Munn, Denver, presiding. In his address he advocated a school of instruction for the training of health officers. He said that physicians did not advocate vaccination for commercial benefits because it would be more profitable financially to the physician to let smallpox attack as many patients as possible. The following officers were elected: Dr. Richard W. Corwin, Pueblo, president: Drs. William W. Grant, of Denver, P. J. McHugh, of Fort Collins and Z. J. Forhan, of Trinidad, vice-presidents; Dr. James M. Blaine, Denver, corresponding secretary; Dr. Minnie C. T. Love, Denver, recording secretary, and Dr. William J. Rothwell, Denver, treasurer. The 1902 meeting will be held in Pueblo.

CHICAGO SOCIETY OF INTERNAL MEDICINE.

Annual Meeting, June 27, 1901.

The president, Dr. John A. Robison, in the Chair.

Causation, Effects, Prophylaxis and Management of Biliary Calculi.

Dr. I. N. Danforth said that the most common cause of biliary calculi was a catarrhal inflammation of the gall ducts. He detailed a case, the wife of a minister, who thought she was going to die of cancer of the liver. She presented no symptoms of that disease, but her case was clearly one of inflammation of the liver with subacute nephritis of several years duration. Patient manifested all the symptoms of gallstones. He operated and found stones in the hepatic duct, not in the gall bladder. Patient died a short time after the operation. Post-mortem examination disclosed considerable enlargement of the liver, and the ramifications of the gall ducts were filled with a thick, tenacious mucus, precipitated crystals of salts, and a number of small calculi.

He reported another case which came under his observation ten years ago, in which a diagnosis of floating kidney was made. The patient was sent to him for operation. He operated, expecting to find a floating kidney, but when he reached the position where the kidney ought to be, he found it was not the kidney at fault, but a floating liver. He evacuated a pint or more of thickened bile. Four gallstones were found in the common duct and removed. A biliary fistula followed the operation, so that bile escaped through it for a month or more afterwards, but the fistula gradually closed up, and the patient recovered, with the exception that she had an enlarged or hypertrophied liver, and had occasionally bilious attacks, during which time there was more or less tenderness over the liver. This case of gallstones had its inception in a chronic catarrhal inflammation of the gall ducts.

Dr. M. L. Goodkind thought that catarrhal conditions of the gastro-intestinal tract were predisposing factors in producing gallstones, constituting a suitable soil for the development of organisms within the bowel. The colon bacillus was not infrequently found in the gall bladder as a direct cause, the catarrhal condition simply operating as a predisposing factor. It was found after typhoid fever. He had had several cases operated on, in which there seemed to be a direct history following typhoid fever. He had seen three or four cases of gallstones at the Michael Reese Hospital which were directly due to mitral stenosis. In an English text-book mitral stenosis was mentioned as a frequent cause of gallstones, the statistics given by Gibson being that gallstones occurred in about 6 per cent. of all women, and in from 20 to 26 per cent. of all men, having mitral stenosis.

Another condition which was frequently associated with gallstones, is Glenard's disease of enteroptosis and gastroptosis, but whether that was due to the same cause that brought on gallstones, as tight lacing and debility, or whether it was a direct cause, he did not know.

Prophylaxis consisted in keeping the gastro-intestinal tract in as good condition as possible during the acute infectious diseases, particularly those that manifested themselves in the intestinal tract. The diet should be carefully watched. People predisposed to mitral stenosis should pay attention to the action of the liver: to the action of the intestinal canal. The bowels should be flushed for a month or so after an infectious disease, such as typhoid fever, particularly where constipation existed, by the occasional use of phosphate of soda, intestinal antiseptics, benzoate of soda and salicylate of soda being preferred by most authorities.

His own experience, in the management of biliary calculi, had been favorable to medical treatment. He had gone through the Carlsbad treatment of his patients, using phosphate of soda, rhubarb, etc. In the management of biliary calculi during the attack, to relieve pain he had resorted to Hoffman's drops, hot fomentations, and various external remedies, but had never found them successful. He had relied, during the attack, on whiffs of chloroform.

Dr. Liston H. Montgomery referred to the surgical treatment of biliary calculi and spoke of cholecystotomy, saying that this operation was first proposed in 1733. At that time the operation was considered feasible by French, German, and English surgeons.

Dr. Edward F. Wells stated that the first recorded operation for gallstones, deliberately undertaken, was made by Bobbs, of Indianapolis, Ind., some time before 1870. A few years after that, and before Dr. Bartholow operated, Dr. Marion Sims advocated strongly and operated for gallstones. He remembered the circumstances particularly, for the reason that in the year 1876 his attention was called to an article published in the *Boston Medical and Surgical Journal*, by a Baltimore physician, entitled, "A Medical Reclamation from Surgery in the Treatment of Gallstones." In this article choloroform was advocated as an internal remedy. Cholecystotomy had already been established in medical practice previous to 1876. He had prescribed chloroform from the time he read the article referred to to the present day. If chloroform was any benefit in the treatment of gallstones, it acted as a solvent of them. But it might be beneficial in other ways. It might promote secretion of bile; it might promote fluidity of the bile and prevent the formation of gallstones. He believed chloroform was a very useful agent. He was positive that his patients were not mistaken about the benefits which they had derived from taking chloroform for a long period. One of his patients had taken it week after week, and month after month for 15 years, and he did not think patients would continue any one remedy any such length of time as he had seen patients do with chloroform without believing they had received benefit from it. Gallstone colic, from which patients suffered, might be due to a single stone which was dislodged, and the patient might take chloroform or anything else and not have another attack. A patient might have an attack of gallstone colic and never have another, so that because apparent benefit had been derived, it did not follow that real benefit had accrued. The remedy was certainly a harmless one, and he still prescribed it. He gave it in from 10 to 20 drop doses, three times a day, in cream or syrup. Patients were able to take it indefinitely, and after taking it for a year or so they would ask if there was any harm in continuing it, and, if not, they would continue to use it. In answer to the question whether there was any danger of patients acquiring the chloroform habit, Dr. Wells replied that he did not think so, and again called attention to the case of the man who had taken it for fifteen years.

Recently he had a patient who was taken ill with severe abdominal pain, followed by nausea and vomiting. He saw him the next morning, at which time the patient placed his hand in the lower part of the abdomen on the right side above Poupart's ligament. This region was very tender. Temperature was 101; pulse moderately accelerated. He made a probable diagnosis of appendicitis. A blood count was made showing moderate leucocytosis. No uranalysis was made, and there was no bile present in the urine. There was no jaundice. At the end of three days he was free from pain and fever, although the slight tenderness in the region referred to continued. On the fourth day patient went to his place of business in Hammond, walked a considerable distance, returned home not feeling so well. The next morning, at 4:30, he was seized with excruciating pain in the abdomen. The speaker was sent for. He found the man rolling in bed on his hands and occupying every imaginable position on account of agonizing pain. The pain had returned and was of the same character as that from which he had suffered four or five days before. He said to himself that no man with appendicitis was going to roll on the bed and get on his hands and knees, while a man with gallstone colic might do so. Here was a diagnostic point of value. It was easy to conclude as to the nature of the affection. Pain and tenderness in the lower portion of the abdomen returned, and in fact tenderness had never disappeared. Fever recurred. The pulse became accelerated. Patient vomited once or twice, but had no jaundice, no bile in the urine. The gall bladder was opened, and a number of gallstones removed. At a secondary operation a number of very large gallstones were removed, probably twenty large ones, and a large number of small ones. An unusual feature in this case was a localized peritonitis occupying the right half of the abdomen, extending down as far as the iliac fossa and nearly to the median line, spread out almost as large as the hand, containing a considerable amount of flocculent serum. It was walled off from the general abdominal cavity, and did not contain bile, although the gall bladder lay in immediate juxtaposition to this.

Dr. George W. Webster directed attention to a number of points in regard to the symptomatology. He said we should distinguish carefully between those cases in which there was a stone or multiple stones in the common duct, and those in which there was obstruction due to stones or a stone in the cystic duct. The symptomatology in both of these cases was rather characteristic, and each one furnished peculiar clinical features that were of interest and served to distinguish readily one from the other. In those cases in which there was a stone in the common duct, particularly a movable stone, having the ball-valve action first described by Osler, we might have two sets of symptoms. The blood-pressure in the portal vein was the lowest perhaps of any vein in the body. There were three other veins spreading out from this through which collateral circulation might be established where there was increased pressure in the portal vein. For example, the inferior hemorrhoidal, the superior epigastric and the azygos veins were the ones to which he referred. When for any cause there was increased obstruction in the liver, therefore diminished celerity of flow of blood in the liver, this led to increased pressure in the portal vein. This would immediately cause a diversion of a part of the blood stream which should pass through the liver through the collateral circulation, and we had symptoms due to substances, such as the products of proteid digestion, peptone, and the like, in the blood, with extreme lowering of blood tension, mental depression, and other symptoms which were characteristic of toxemia merely due to a normal blood stream which should have these substances removed by passing through the liver. In other words, we had symptoms similar to those which snake poisoning would produce if injected into the systemic circulation without passing through the portal vein. We had added to that certain causes in which there was real infection. There might be symptoms of infection, and oftentimes added to both of these there might be a picture of cholemia. The clinical picture was a composite one. If we interpreted the symptoms rightly, in the majority of cases we could tell whether there was merely a cholemia, an obstruction of the portal circulation, or a more extensive obstruction in that region. For example, it was known that the circulatory activity of the liver depended largely on the chemistry of digestion. Where there was alcoholic gastritis, or gastritis from any other cause, we would have increased activity of the liver due to the increased chemical activity of the digestive organs. This led to increased pressure in the liver, increased pressure in the portal circulation, and we had this diversion of the blood from the collateral channels, and the symptoms found under those circumstances were due to the influence of the blood, which should have passed through the liver, being diverted and acting on a susceptible nervous system.

In regard to the treatment, he was long ago convinced that there was only one treatment, namely, a surgical operation. If the patient could not be relieved by medicinal means, the physicians should refer him to a surgeon.

Dr. Liston H. Montgomery asked in regard to treating biliary calculi with large doses of olive oil. In a few instances he had used sweet oil with great benefit. He hardly knew whether the oil was a solvent or whether it assisted the passage of the stones on through the ducts into the intestine.

Dr. Goodkind said that he had used it, but without good results.

Dr. Goodkind said that he had yet to see the first case of genuine gallstones that had been cured by olive oil either given by the mouth or per rectum.

Dr. Wells said that surgical treatment was the proper method of managing gallstones. However, neither medical nor surgical treatment alone was the best and proper management for every case. It was within the experience of every member of the Society to have had patients who had had attacks of gallstone colic and who, through many years, had never had another attack. Gall bladders had been opened post-mortem, with but a single gallstone present, or but few or no gallstones present in cases in which gallstones had been diagnosed. If a patient recovered from an attack of biliary colic, and was in good health, he did not think he or she should be operated on. It was well to keep such patients under observation, and if frequent attacks of biliary colic occurred, then they should be operated.

Dr. John A. Robison said that the frequency with which gallstones followed typhoid fever called to his mind an interesting case which he saw in the Presbyterian Hospital. The patient had had an attack of typhoid fever ten years previously. Dr. Bevan operated and found a number of gallstones; also a suppurative cholangitis. A test was made and the Widal reaction was very prompt.

He saw Dr. Fenger also examine a case in his clinic, which was supposed to be one of appendicitis, and diagnosed as such by two or three good surgeons. Dr. Fenger was inclined to think that the diagnosis was correct, but expressed some doubt to the class as to whether the case was really one of appendicitis or of gallstones. He opened in the region of the gall-bladder first. On reaching the gall-bladder, he readily discovered the gallstones, removed them, and the patient got well.

As regards the administration of olive oil, he had used it frequently with no results. In fact, in one case he believed it was the cause of death. The patient was 50 years of age, and had previously been operated on by the late Dr. Parkes for renal calculus. The calculus was removed, a fistula resulted, and did not close. Shortly after the operation for the removal of renal calculus, the woman developed symptoms of biliary calculi. She had frequent attacks of biliary colic, and the speaker was called to see her one night during one of the attacks. He called in a surgeon, as he thought the case was urgent, who advised immediate operation. The family were loth to consent to operation. A physician was called and placed the woman on the olive oil treatment. In less than four weeks afterwards the woman went into collapse and died. Postmortem examination disclosed a very large gallstone imbedded in the common duct, which had ulcerated its way through the outer and middle coats of the cystic artery. If the patient had been operated on at the time he thought she would have been relieved.

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Dr William H. Welch in the Chair.

Splenomegaly.

Prof. Wm. Osler showed a case of splenomegaly associated with cirrhosis of the liver, in a young man who has been a beer-drinker. He has had occasional attacks of jaundice since early life. Such tumors are often removed for ovarian tumors. The three earliest cases of splenectomy were done by gynecologists. Several other cases were referred to by Dr. Osler, as 1, lasted eight or ten years, and patient recovered completely; 2, spleen was removed, and patient did well for more than a week, then had recurrence of his frequent attacks of hemorrhage, with fatal result; 3, had nearly bled to death on four or five occasions; died from uncontrollable hemorrhage a few minutes after being taken from the operating table.

Scurvy.

This was in a white man accompanied with subcutaneous hemorrhage of the thigh, which was in a scleremic or sclerotic condition. The patient had come in with hemorrhages, swollen gums and enlarged knee. On aspirating the latter a bloody fluid was obtained. There were remains of a purpuric rash. It is an unusual condition which has been described by Russian physicians. A good deal of scurvy comes into the hospital from the large number of foreign immigrants, especially Hungarians and Poles.

Cystitis—Peculiar Condition of Uterus in Pregnancy.

Dr. Howard A. Kelly spoke of drainage in bad cases of cystitis. Here attempts to wash out will be cut short on account of the pain. Dr. Kelly treats such cases by placing the patient in the knee-breast position and letting air into the bladder through the cystoscope. He then thrusts in a narrow-bladed, specially made knife, set at an angle with the handle, and draws it downward towards the urethra, leaving a free opening into the bladder for escape of urine. Dr. Kelly urged the importance of making topical examination of the bladder before commencing treatment in cases of apparent cystitis. He had had cases which had been treated elsewhere for a length of time for cystitis when on using the cystoscope a stone was seen, and in its removal the symptoms disappeared. He spoke also of peculiar cases of pregnancy which he does not understand. One part of the uterus softens down and the rest remains rigid; the softened part may bulge. In his case it was mostly towards the patient's right. The patient was the wife of a physician from Iowa. He was advised to let it alone and returned home, where his wife had a normal labor. In another case, the wife of an army surgeon, the abdomen was opened and the right upper horn of the uterus found to be softened. The patient later aborted per vias noturales. In a third case exactly the same condition was found. Dr. Kelly would call it "Apical pregnancy," and it is liable to be mistaken for extrauterine pregnancy.

Experience with an Epidemic of Smallpox.

Dr. Otley J. Porter, of Columbia, Tenn., described an epidemic that has recently prevailed in that section of Tennessee in which he lives. For a time the diagnosis was in dispute, some regarding it as chicken-pox, others as a new sort of eruption, "the bumps," and a few diagnosticating true smallpox. Meanwhile, in the uncertainty there was no efficient action or isolation, and the disease spread until there were 1000 cases. Dr. Porter exhibited casts of the eruption and threw pictures on the screen, showing that the disease differed in no way from the smallpox of the text-books, there being cases of hemorrhagic, confluent, semi-confluent and discrete smallpox, as in other epidemics. The mortality also was the same, all the hemorrhagic cases (5 or 6) dying; 40 per cent. of the confluent, and 10 to 15 per cent. of the discrete. Old persons over 75, pregnant women and infants under 12 months are usually exempted from the need of vaccination, but none need it more than these persons. In the 1000 cases there were some 15 of the disease in the fetus *in utero*, several of which Dr. Porter had himself delivered.

Dr. Smith, of Minneapolis, spoke of an epidemic of 600 cases in that city. Fifty cases had occurred before the existence of smallpox was acknowledged by the authorities. The fatality was small. Of the 6 cases in pregnant women, all aborted and died. Many who were vaccinated took vaccinia. Less than 2 per cent. showed a scar.

Dr. Osler said that the present widespread epidemic was evidently one of exceptional mildness, but it is a mistake to suppose that discrete epidemics are rare; Sydenham describes them.

Dr. Porter said the idea of an "attenuated" organism was not borne out by the facts, for example these cases of hemorrhagic, confluent and discrete form, all originated from the same case.

STATE MEDICAL SOCIETY OF WISCONSIN.

The fifty-fifth annual meeting held at Waukesha, June 26, 27 and 28, 1901.

The president, Dr. J. F. Pritchard, of Manitowoc, in the chair.

Serotherapy.

Dr. J. F. Pember, of Janesville, said that the mortality in all cases of tetanus treated without tetanus antitoxin is 60 per cent., as against 30 per cent. for all cases treated with it. The serum treatment in cholera and plague is practically without data. The treatment of rabies by the Pasteur method results in an enormously lessened mortality.

The treatment of plague by serotherapy has not shown results warranting any conclusion. The antipneumonia serum promises much. No very useful results have been reached in the serum treatment of tuberculosis. Antispirochetic serum has shortened the disease some days in the treatment of relapsing fever. Serum treatment in malignant endocarditis promises much. The treatment of snake bites by antivenomous serum is largely in its experimental stage. In cases of streptococcus infection the serum treatment has shown some good results. But the antitoxin treatment of diphtheria has won for itself the right to be regarded as a specific. Bayeux's tables, based on an analysis of 200,000 cases, give 55 per cent. as the death-rate before the advent of antitoxin and 16 per cent. since its use, with not a single death due to the antitoxin. The American Pediatric Society's table shows that where antitoxin is injected the first day of the disease the mortality is 6.6 per cent., the second day 8.3, the third 12.9, the fourth 17, and the fifth 23.2 per cent. The writer made the bold statement that the piosonous dose of antitoxin has not been found and that in the near future physicians will adopt heroic measures in desperate cases and give enormously large doses.

Chorea.

Dr. H. B. Favill, of Chicago, read a paper on chorea, with special reference to its relationship with rheumatism and heart disease. He called attention to the fact that the problem was an obscure one. The word functional is frequently misused. It really is an expression of one of two views, either describing a reaction whose structural basis is unknown or as implying the possibility of resistance to morbid influence without permanent organic change. Endocarditis is really rheumatism and not a sequela of it, and is essentially the rheumatism of the young; the evidence is accumulating that rheumatism is a septic process. The probable conclusion is that endocarditis, chorea and arthritis are coördinate manifestations of diseased conditions peculiar to the young, in that order, and that an important element in the causation is infection.

Conjunctivitis, Keratitis and Iritis.

Dr. G. V. Mears, of Fond du Lac, read a paper on differential diagnosis and treatment of conjunctivitis, keratitis and iritis. He treated the matter from the standpoint of the general practitioner. Ophthalmia of the newborn especially must come under the treatment of the general practitioner and he should be able to make a differential diagnosis, but a good rule is when in doubt call a specialist, and in fact the general practitioner should not, unless compelled to do so, treat important affections of the eye.

Bright's Disease and Diabetes Mellitus.

Dr. A. J. Hodgson, of Waukesha, read a paper on clinical points in Bright's disease and diabetes mellitus. He suggested a bread made of 20 per cent. nut-meats with 80 per cent. pulverized bran, sweet milk, baking powder, a little butter and egg. Bake in the form of gems. The so-called gluten flour is usually a fraud. It is only a cheap quality of flour which the mills are glad to get rid of at any price. Drugs are of little benefit. Codein will not cure. As to Bright's disease, the point is to get the whole system in good order, aside from the kidneys. Then the kidneys will soon come into line. It is especially important to keep the urine bland, which may be accomplished by the use of proper waters.

Fractures of the Femur.

Dr. F. J. Ford, of Omro, read a paper on the subject of fractures of the middle and upper third of the femur. Results show that functionally useful limbs are not obtained in more than 16 per cent. of cases, while perfect results are almost never obtained.

Neurasthenia.

Dr. J. H. McBride, of Pasadena, California, read a paper on "Some points in the management of the neurasthenic." The writer emphasized the importance of the physician getting hold of the mentality of his patient and always bearing in mind that these patients are people who need to be recreated in character and habits of mind and body.

Dr. Harold N. Moyer, of Chicago, said that hysteria, neurasthenia and hypochondria must not be confounded. Hypochondria is simply a delusion of illness while hysteria and neurasthenia are true diseases. In neurasthenia the fatigue symptom is crucial. It is very important to obtain mental control of the patient.

Reorganization.

The President in his Annual Address strongly urged the adoption of a new constitution of reorganization of the Society, following in line with the American Medical Association, and making the unit the county or local medical association. Under this plan, he said, the profession of the state presents an unbroken front which secures the greatest possible good to the community and makes quackery almost impossible. Under the plan presented the business of the Society is done by delegates who have charge of all matters except the scientific program. The members of this House of Delegates are ineligible to office, which puts the working part of the Association out of politics.

The President recommended for immediate action, 1, that three or more members of the Society be elected to act as a reorganization committee with full powers to make such changes as may be necessary in the constitution and by-laws of this Society, to conform to the plan of reorganization of the American Medical Association, their report to be ready for adoption at the next annual meeting of this Society. This recommendation was adopted. The reorganization committee named is as follows: Dr. J. F. Pritchard, of Manitowoc, Dr. W. B. Hill, of Milwaukee, and Dr. G. V. Mears, of Fond du Lac; 2, to elect delegates at this session to comply with the requirements for representation in the House of Delegates of the American Medical Association. This was done on the following Friday.

Nervous Diseases Following Injuries.

Dr. T. W. Nuzum, of Brodhead, presented the results of numerous experiments and concluded that slight injuries may produce severe spinal neuroses; that bodily injury is often less important than the fright element; that the majority of cases against great corporations are either feigned or exaggerated; that it is the duty of the expert witness to determine the existence of actual disease and its character, whether simply neurasthenia, severe hysteria, or organic lesion; that prognosis is usually good; that traumatic hysteria is intractable; that death may result where no physical lesion can be demonstrated; that traumatism may cause locomotor ataxia, epilepsy, apoplexy or paralysis agitans. Many of the cases, however, are due to suggestion.

Address in Medicine.

Dr. George M. Gould, of Philadelphia, delivered the annual address in medicine on the relation between sin and disease. He said that the unvarying concomitant of civilization was syphilization. It is claimed that 50 per cent. of wives' sterility is due to the husbands' gonorrhea. The licensing of evil is the lessening of evil. The annual drink bill of the United States is $1.050.000.000. The chief cause of crime is alcohol. The Royal Commission of Scotland attributes 72 per cent. of all crime directly or indirectly to alcohol. Prohibition breeds intemperance and is a hypocritical failure. In prohibition Vermont 3,000,000 doses of opium were demanded last year. The diseases caused in whole or in part by sin are in this order: syphilis, gonorrhea, alcoholism, abortion, tabes, insanity, hysteria, etc. Deaths caused in whole or in part by sin are found to be in this order: suicide, homicide, syphilis, gonorrhea, war, famine, pestilence alcoholism, etc. The horror of the crimes of the civilized soldiery in China is unknown. Thirty to forty per cent. of blindness is due to gonorrhea. Pneumonia is now killing more of our citizens than pulmonary tuberculosis. Nearly one-half of our mortality is due to disease of the lungs and 75 per cent. of this mortality is preventable. The average length of life in the 16th century was between 18 and 20 years. To-day it is over 40 years. In the last 20 years it has been lengthened by six years. Our toleration of anti-vaccinationists, Eddyism and Dowieism is to be paid for in millions of lives. Only one out of three thousand millionaires cares a fig for the prevention of disease. All honor to the one! Three billion dollars is the loss to the American people by preventable deaths each year. These figures warrant a demand for the establishment of a National Bureau of Health with a cabinet officer at its head. Such a bureau would easily save a thousand times its expense. Of course, it is the saving in life and suffering that is aimed at, but the figures are given to bring the matter home to your imaginations.

Causes of Sudden Death.

Dr. J. M. Beffel, of Milwaukee, said that the subject is important. Post-mortems should always be had and physicians should be careful in giving death certificates. The Doctor reviewed a statistical record of 100 cases of sudden death which occurred in Milwaukee during the past three years. Alcohol is a very important factor in sudden death. Forty-seven cases of the 100 were due to diseased condition of the vascular system. The kidneys were diseased in 22 cases, the lungs in 18, the liver in 9. There were three classes of sudden deaths due, 1, to diseases of the vascular system; 2, to general intoxication, such as diseases of the lungs, liver and kidneys, and 3, rupture of blood vessels within the brain.

Address in Surgery.

Dr. John B. Deaver, of Philadelphia, presented the annual address on the subject of "The atypical and unusual varieties of appendicitis and their management." He said, there are three cardinal symptoms of diagnosis, pain, tenderness and rigidity. Many cases are difficult of differential diagnosis, especially chronic cases, but the treatment of this disease is essentially operative, and the earlier the operation the better. Indigestion and biliousness are frequently attributable to appendicitis. The importance of a careful history of the case can not be exaggerated.

Cervical and Perineal Lacerations.

Dr. W. E. Ground, of West Superior, said that nearly all of the diseases occurring during labor follow in the wake of the midwife. Dr. Harris' operation is the coming one. Repair perineal lacerations immediately, except deep-seated lacerations of the cervix, where repair should be postponed for some time in order to avoid sepsis.

Acute Pain in Abdominal Disease.

Dr. A. J. Burgess, of Milwaukee, read a paper on the diagnostic importance and significance of acute pain in abdominal disease. He emphasized the importance of prompt action in cases where pain in the abdominal cavity is accompanied by rigidity, or even shock without rigidity. Dr. Burgess insisted on the importance of immediate operation where a man has all the symptoms of a grave abdominal disease.

Earache.

Dr. G. A. Heidner, of West Bend, read a paper on the subject of earache, its significance and remedy, discussing the most important causes of earache, viz., trouble in the external canal, and trouble behind the drum-head. He opposed paracentesis by the general practitioner in children under 10 years of age.

Cleft Palate.

Dr. George V. I. Brown, of Milwaukee, read a paper on the subject of surgical treatment of cleft palate and proposed what is in many respects a new operation, which he has sucrhage, with fatal result; 3, had nearly bled to death on four or five occasions; died from uncontrollable hemorrhage a few minutes after being taken from the operating table.

Scurvy.

This was in a white man accompanied with subcutaneous hemorrhage of the thigh, which was in a scleremic or sclerotic condition. The patient had come in with hemorrhages, swollen gums and enlarged knee. On aspirating the latter a bloody fluid was obtained. There were remains of a purpuric rash. It is an unusual condition which has been described by Russian physicians. A good deal of scurvy comes into the hospital from the large number of foreign immigrants, especially Hungarians and Poles.

Cystitis—Peculiar Condition of Uterus in Pregnancy.

Dr. Howard A. Kelly spoke of drainage in bad cases of cystitis. Here attempts to wash out will be cut short on account of the pain. Dr. Kelly treats such cases by placing the patient in the knee-breast position and letting air into the bladder through the cystoscope. He then thrusts in a narrow-bladed, specially made knife, set at an angle with the handle, and draws it downward towards the urethra, leaving a free opening into the bladder for escape of urine. Dr. Kelly urged the importance of making topical examination of the bladder before commencing treatment in cases of apparent cystitis. He had had cases which had been treated elsewhere for a length of time for cystitis when on using the cystoscope a stone was seen, and in its removal the symptoms disappeared. He spoke also of peculiar cases of pregnancy which he does not understand. One part of the uterus softens down and the rest remains rigid; the softened part may bulge. In his case it was mostly towards the patient's right. The patient was the wife of a physician from Iowa. He was advised to let it alone and returned home, where his wife had a normal labor. In another case, the wife of an army surgeon, the abdomen was opened and the right upper horn of the uterus found to be softened. The patient later aborted per vias noturales. In a third case exactly the same condition was found. Dr. Kelly would call it "Apical pregnancy," and it is liable to be mistaken for extrauterine pregnancy.

Experience with an Epidemic of Smallpox.

Dr. Otley J. Porter, of Columbia, Tenn., described an epidemic that has recently prevailed in that section of Tennessee in which he lives. For a time the diagnosis was in dispute, some regarding it as chicken-pox, others as a new sort of eruption, "the bumps," and a few diagnosticating true smallpox. Meanwhile, in the uncertainty there was no efficient action or isolation, and the disease spread until there were 1000 cases. Dr. Porter exhibited casts of the eruption and threw pictures on the screen, showing that the disease differed in no way from the smallpox of the text-books, there being cases of hemorrhagic, confluent, semi-confluent and discrete smallpox, as in other epidemics. The mortality also was the same, all the hemorrhagic cases (5 or 6) dying; 40 per cent. of the confluent, and 10 to 15 per cent. of the discrete. Old persons over 75, pregnant women and infants under 12 months are usually exempted from the need of vaccination, but none need it more than these persons. In the 1000 cases there were some 15 of the disease in the fetus *in utero*, several of which Dr. Porter had himself delivered.

Dr. Smith, of Minneapolis, spoke of an epidemic of 600 cases in that city. Fifty cases had occurred before the existence of smallpox was acknowledged by the authorities. The fatality was small. Of the 6 cases in pregnant women, all aborted and died. Many who were vaccinated took vaccinia. Less than 2 per cent. showed a scar.

Dr. Osler said that the present widespread epidemic was evidently one of exceptional mildness, but it is a mistake to suppose that discrete epidemics are rare; Sydenham describes them.

Dr. Porter said the idea of an "attenuated" organism was not borne out by the facts, for example these cases of hemorrhagic, confluent and discrete form, all originated from the same case.

STATE MEDICAL SOCIETY OF WISCONSIN.

The fifty-fifth annual meeting held at Waukesha, June 26, 27 and 28, 1901.

The president, Dr. J. F. Pritchard, of Manitowoc, in the chair.

Serotherapy.

Dr. J. F. Pember, of Janesville, said that the mortality in all cases of tetanus treated without tetanus antitoxin is 60 per cent., as against 30 per cent. for all cases treated with it. The serum treatment in cholera and plague is practically without data. The treatment of rabies by the Pasteur method results in an enormously lessened mortality.

The treatment of plague by serotherapy has not shown results warranting any conclusion. The antipneumonia serum promises much. The President recommended for immediate action, 1, that three or more members of the Society be elected to act as a reorganization committee with full powers to make such changes as may be necessary in the constitution and by-laws of this Society, to conform to the plan of reorganization of the American Medical Association, their report to be ready for adoption at the next annual meeting of this Society. This recommendation was adopted. The reorganization committee named is as follows: Dr. J. F. Pritchard, of Manitowoc, Dr. W. B. Hill, of Milwaukee, and Dr. G. V. Mears, of Fond du Lac; 2, to elect delegates at this session to comply with the requirements for representation in the House of Delegates of the American Medical Association. This was done on the following Friday.

Nervous Diseases Following Injuries.

Dr. T. W. Nuzum, of Brodhead, presented the results of numerous experiments and concluded that slight injuries may produce severe spinal neuroses; that bodily injury is often less important than the fright element; that the majority of cases against great corporations are either feigned or exaggerated; that it is the duty of the expert witness to determine the existence of actual disease and its character, whether simply neurasthenia, severe hysteria, or organic lesion; that prognosis is usually good; that traumatic hysteria is intractable; that death may result where no physical lesion can be demonstrated; that traumatism may cause locomotor ataxia, epilepsy, apoplexy or paralysis agitans. Many of the cases, however, are due to suggestion.

Address in Medicine.

Dr. George M. Gould, of Philadelphia, delivered the annual address in medicine on the relation between sin and disease. He said that the unvarying concomitant of civilization was syphilization. It is claimed that 50 per cent. of wives' sterility is due to the husbands' gonorrhea. The licensing of evil is the lessening of evil. The annual drink bill of the United States is $1.059.000.000. The chief cause of crime is alcohol. The Royal Commission of Scotland attributes 72 per cent. of all crime directly or indirectly to alcohol. Prohibition breeds intemperance and is a hypocritical failure. In prohibition Vermont 3.000.000 doses of opium were demanded last year. The diseases caused in whole or in part by sin are in this order: syphilis, gonorrhea, alcoholism, abortion, tabes, insanity, hysteria, etc. Deaths caused in whole or in part by sin are found to be in this order: suicide, homicide, syphilis, gonorrhea, war, famine, pestilence alcoholism, etc. The horror of the crimes of the civilized soldiery in China is unknown. Thirty to forty per cent. of blindness is due to gonorrhea. Pneumonia is now killing more of our citizens than pulmonary tuberculosis. Nearly one-half of our mortality is due to disease of the lungs and 75 per cent. of this mortality is preventable. The average length of life in the 16th century was between 18 and 20 years. To-day it is over 40 years. In the last 20 years it has been lengthened by six years. Our toleration of anti-vaccinationists, Eddyism and Dowieism is to be paid for in millions of lives. Only one out of three thousand millionaires cares a fig for the prevention of disease. All honor to the one! Three billion dollars is the loss to the American people by preventable deaths each year. These figures warrant a demand for the establishment of a National Bureau of Health with a cabinet officer at its head. Such a bureau would easily save a thousand times its expense. Of course, it is the saving in life and suffering that is aimed at, but the figures are given to bring the matter home to your imaginations.

Causes of Sudden Death.

Dr. J. M. Beffel, of Milwaukee, said that the subject is important. Post-mortems should always be had and physicians should be careful in giving death certificates. The Doctor reviewed a statistical record of 100 cases of sudden death which occurred in Milwaukee during the past three years. Alcohol is a very important factor in sudden death. Forty-seven cases of the 100 were due to diseased condition of the vascular system. The kidneys were diseased in 22 cases, the lungs in 18, the liver in 9. There were three classes of sudden deaths due, 1, to diseases of the vascular system; 2, to general intoxication, such as diseases of the lungs, liver and kidneys, and 3, rupture of blood vessels within the brain.

Address in Surgery.

Dr. John B. Deaver, of Philadelphia, presented the annual address on the subject of "The atypical and unusual varieties of appendicitis and their management." He said, there are three cardinal symptoms of diagnosis, pain, tenderness and rigidity. Many cases are difficult of differential diagnosis, especially chronic cases, but the treatment of this disease is essentially operative, and the earlier the operation the better. Indigestion and biliousness are frequently attributable to appendicitis. The importance of a careful history of the case can not be exaggerated.

Cervical and Perineal Lacerations.

Dr. W. E. Ground, of West Superior, said that nearly all of the diseases occurring during labor follow in the wake of the midwife. Dr. Harris' operation is the coming one. Repair perineal lacerations immediately, except deep-seated lacerations of the cervix, where repair should be postponed for some time in order to avoid sepsis.

Acute Pain in Abdominal Disease.

Dr. A. J. Burgess, of Milwaukee, read a paper on the diagnostic importance and significance of acute pain in abdominal disease. He emphasized the importance of prompt action in cases where pain in the abdominal cavity is accompanied by rigidity, or even shock without rigidity. Dr. Burgess insisted on the importance of immediate operation where a man has all the symptoms of a grave abdominal disease.

Earache.

Dr. G. A. Heidner, of West Bend, read a paper on the subject of earache, its significance and remedy, discussing the most important causes of earache, viz., trouble in the external canal, and trouble behind the drum-head. He opposed paracentesis by the general practitioner in children under 10 years of age.

Cleft Palate.

Dr. George V. I. Brown, of Milwaukee, read a paper on the subject of surgical treatment of cleft palate and proposed what is in many respects a new operation, which he has successfully performed in many cases. He said the most important point in the diagnosis was to make a proper classification of cases. Dr. B. G. Maercklein of Milwaukee said that Dr. Garretson of Philadelphia first called attention to the fact that the bones in infants were so soft that they could be strung into apposition.

Syphilis of the Nose and Throat.

Dr. Henry B. Hitz, of Milwaukee, urged that the profession do not neglect a careful and frequent examination of the nose and throat. If the patient complains of nasal discomfort, obstruction or discharge, or of any symptoms referable to the throat and vocal organs, find out the cause if possible. If after examination you are still in doubt as to the specific character of the lesion, put your patient on a rigorous specific treatment—preferably a mixed treatment—which will clear up your doubts in short order, and without the possible mutilating results of delay.

Commissions in Medicine.

Dr. Carl L. Feld, of Watertown, read a paper on commissions in medicine from a moral and medicolegal standpoint. It was stated in the discussion of the paper that there was very little trouble of the kind in Wisconsin. That the matter was gradually righting itself, and that the proper principle to apply was to determine whether or not there was collusion between the general practitioner and the specialist.

Milwaukee was chosen as the place of the next meeting. The officers for the ensuing year are as follows: President, W. H. Neilson of Milwaukee; first vice-president, A. J. Hodgson of Waukesha; second vice-president, L. H. Pelton of Waupaca; secretary, Charles S. Sheldon of Madison; treasurer, Sidney S. Hall of Ripon; censors, F. E. Walbridge of Milwaukee, H. Reineking of Sheboygan, and George M. Steele of Oshkosh.

Delegate to the council of the American Medical Association for three years, W. T. Sarles of Sparta; alternate, Herman Gasser of Platteville; for one year, J. R. Barnet of Neenah; alternate, Byron M. Caples, of Waukesha.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, held June 10, 1901.

The president, Dr. N. P. Dandridge, in the chair.

Use and Abuse of Digitalis.

Dr. Robert Ingram went fully into the discussion of the properties of the drug, its various active principles, and the therapeutic indications. He was followed by Dr. Frank Scheerer, who gave a detailed account of several cases illustrating the various organic valvular diseases which had been materially benefited by the judicious administration of digitalis.

Dr. L. A. Moloney said that while an interne in the Cincinnati Hospital, a patient had fallen suddenly to the floor. He happened to be in the ward at the time and on examination found the heart's action had almost ceased. He had immediately given a hypodermic injection of 1/30 grain of digitalin, and had repeated the dose in a few minutes. After the first injection there had been a slight fluttering of the heart, but after a few seconds the action of the heart was found to be more regular. Within half an hour after the last injection the patient was able to move about the ward. Recently he had had occasion to use digitalin on a patient afflicted with a severe diarrhea. The dose in this instance was 1/50 of a grain, and the result was all that could be desired.

Dr. William H. Muhlberg was inclined to think that digitalin was entirely inert, and gave an experiment in which he had used the drug on a rabbit with negative results; with the tincture of digitalis there resulted a marked increase of the heart's action and contraction of the peripheral vessels.

Dr. S. P. Kramer was inclined to think that this positive reaction with the tincture was due to the alcohol contained in the tincture.

Dr. Muhlberg promised to repeat the experiment and report to the Academy the week following. He made the following report at the regular meeting of the Academy, June 17: "I made the statement last Monday night that I had experimented with some specimens of digitalin and found them absolutely inert, while from a specimen of tincture of digitalis I obtained a distinct rise of blood pressure in a very short time. One of the gentlemen present, in a very able criticism, stated that he did not think that the results obtained from the tincture of digitalis were due to the digitalis, but to the alcohol in the preparation, for the reason that it required in the neighborhood of twenty-four hours to get the characteristic effects of the drug digitalis. I thought his criticism a very fair one and promised to repeat the experiment with digitalis and report later. I obtained some of Merck's digitalin and made a 1 per cent. solution. I then injected 10 gtt. of this solution and waited some thirty minutes, but did not obtain any reaction. I then injected some infusion of digitalis into the jugular vein and obtained a rise of blood-pressure during the first eight or ten beats of the heart immediately succeeding. On the tracing which I will pass around, you will see one line, which is the line of atmospheric pressure, the larger and more distinct line indicates the blood-pressure line. The heart beat was not markedly slowed until after twenty beats. I think the rise in blood-pressure is due to the effect of the drug upon the vasomotor system rather than due to the effect of the drug on the heart itself. The blood-pressure remained up in his experiment about thirty minutes. After killing the animal, I found a typical digitalis heart. The systole was a powerful one, and the heart beat very slowly. I am inclined to think with Dr. Kramer that digitalis does not act on the heart for some time after it is given, but the rise in blood-pressure occurs very shortly after the drug is given, this being due to the effect on the vasomotor system.

Dr. J. L. Cleveland thought that in many cases of heart disease, with congested livers and lungs, the results claimed for digitalis were due in great part to the judicious use of dietetic and hygienic measures. He called attention to the fact that digitalis is often abused and given as soon as a bruit is discovered, when there is really no indication for the exhibition of the drug whatsoever. He did not question the great value of the drug when compensation had been ruptured. He thought that digitalis should be used with great caution when there was a secondary kidney involvement, and especially where the heart was hypertrophied and the arterial tension high; under these circumstances the drug should be put off as long as possible, and when finally administered, should be given in conjunction with some drug as nitroglycerin, which has a tendency to dilate the peripheral vessels and thus lower arterial tone.

Dr. R. B. Hall testified as to the value of Merck's digitalin in heart-failure after abdominal sections, especially where the operation has to be performed on women the subjects of valvular disease of the heart. He wanted to insist that the dose should be as large as 1/20 to 1/15 of a grain and repeated every three or four hours.

Dr. G. A. Fackler thought that the discussion of digitalis should take more the line of personal experience, as at the present time every practitioner can testify as to its value in selected cases. Personally he thought that when compensation was ruptured, no matter what valve was affected, digitalis was indicated. He preferred a reliable tincture, given in doses of from 20 to 30 drops every two to four hours, as indicated by the clinical symptoms. He was no believer in the accumulative action of the drug, so-called, had never seen a case, and on inquiry among a number of his colleagues, had never heard of a case. He had no doubt that a poisonous action could be exerted if the drug were irrationally administered; but digitalis was not peculiar in that regard; all drugs would act in this matter.

Dr. Alfred Friedlander did not agree that the tincture was the only reliable preparation of digitalis. He had obtained good results from the digitalin of Merck and from the fluid extract of Squibb administered hypodermically in one minim doses.

Dr. E. W. Mitchell also testified as to the value of the fluid extract and digitalin. Some months ago he had had occasion to use as much as 1/5 of a grain of digitalin (Merck) in divided doses during the course of an hour's time with the happiest results. He was inclined to think that the infusion of digitalis made by a reliable house gave as satisfactory results as any.

Dr. W. E. Kiely said that as digitalin did not represent the active principle of digitalis, it could not be expected to give the same therapeutic results. He used for the most part a reliable tincture. He did not see why the fluid extract should be superior to the tincture, as the only difference between the two preparations was one of strength. The best results could be obtained from the tincture that is made from the infusion.

COLORADO STATE MEDICAL SOCIETY.

Thirty-first Annual Convention, held in Denver, June 18, 19, and 20, 1901.

Gonorrheal Rheumatism.

Dr. Hobart E. Warren emphasized the following points: Do not treat gonorrheal urethritis by irrigation; do not introduce an instrument into the urethra as long as a discharge or shreds are present. Gonorrheal rheumatism may occur without previous uro-genital infection. Definite points of tenderness about an inflamed joint are peculiar to gonorrheal arthritis. Administer anti-rheumatic remedies at the start; make early use of dry heat.

Mother's Milk.

Dr. Edward C. Hill said that the true test of mother's milk is a grain in weight, about one-half ounce daily, as a rule. Loss of weight as a stationary condition should be an indication for an inquiry into the composition of the milk.

Consideration for the Radical Treatment of Uterine Carcinoma.

Dr. W. A. Jayne has come to the conclusion that when the disease has progressed so far that absolute removal is improbable or problematical, it is much better to discard hysterectomy and resort to the cautery.

Dry Heat in the Treatment of Disease.

Dr. R. W. Corwin described the physiologic influence of dry heat, and related the history of ten cases treated by this method in the Hospital of the Colorado Iron and Fuel Company with beneficial effect. His conclusions are that in surgery it is of great value. He suggested its use in sprains, stiff and tubercular joints, acute nephritis, cramps due to plumbism, arthritis deformans, and acute synovitis.

Case of Typhoid Fever with Greatly Enlarged Liver, and Intestinal Hemorrhages.

Dr. Alfred Mann reported the above case, in which the edge of the liver could be palpated for more than two months after the cessation of the fever, and in which hemorrhages from the bowel occurred on the 4th, 5th, and 6th week of the disease.

National Jewish Hospital for Consumptives.

During the past eighteen months 350 applications for admission were made, of which 228 were examined, and 204 admitted. They are admitted for a term of six months, and no longer than one year. The cases are divided into incipient (25), first (42), second (82), and third (43) stages. Improved 125, unimproved 39; worse 17, died 23. The predominance of right-lung involvement was marked. The largest number were tailors. In 152 cases, the family history was negative. Hemorrhage was present in 98 cases, and spitting of blood in 23 cases; 121 patients had night sweats, in 64 of whom they ceased on coming to Colorado; 92 had never had any; 75 per cent. had fever. In 166 cases bacilli were found; absent in 33 cases; there was no report on the remainder.

Mental Disturbances in the Course of Cardiac Diseases.

Dr. Adolph Zederbaum, after a careful study of many cases in his own practice, and an exhaustive research into the literature of the subject, arrived at the following conclusion: 1, that the heart, in a number of women during pregnancy and the puerperium, is subject to hypertrophy, which may become permanent, and pathologically affect the valves, and 2, that latent cardiac diseases of rheumatic and other origin may first come to the front during pregnancy, or in after labor.

Treatment of Neuralgia with Castor Oil.

Dr. F. E. Waxham reported several cases of facial neuralgia treated successfully with large doses of castor oil. He administered 1 to 3 ounces three or four times daily. After the first two or three doses, it loses its cathartic effect. To make it palatable, he adds mucilage of acacia and lime water.

Bleeding in Radical Operation for Piles.

Dr. Will B. Davis thinks that thorough divulsion from anus to ampulla should be the preliminary step in all operations, and this will prevent post-operative hemorrhage by rendering the muscles incapable of contracting upon the veins, and the same procedure will immediately check a post-operative hemorrhage.

Typhoid Fever.

Dr. W. A. Kickland, of Fort Collins, made the following deduction from a study of "100 Cases of Typhoid Fever Seen in Private Practice During the Fall of 1900": There is a greater similarity in cases infected from a common source than in the same number of cases occurring sporadically; that a rigid milk diet is not absolutely essential to prevent relapse, nor to a low rate of mortality, and that routine use of intestinal antiseptics with hydrotherapy gives as good results as can be obtained from any form of treatment.

Some Experiences with Venesection.

Dr. H. B. Whitney made the following concluding statement: 1, conditions demanding venesection are usually of sudden onset; 2, such cases usually present not only cyanosis, but, also, the local signs of dilated right heart and pulmonary edema; 3, that the gradual heart failure of acute infection and chronic diseases can neither practically nor theoretically be shown to be a proper field for venesection.

Case of Talma's Operation for Ascites in Cirrhosis of Liver.

Dr. M. Ballin reported a case, 53 years old, saloon-keeper; 2 years ago dropsy of extremities; ascites in 1900. He was tapped repeatedly. The parietal peritoneum was greatly scarified with a knife in a semi-circle around the upper angle of the incision and then the omentum was sutured with four stitches to the scarified region. The ascites has not returned. There are about 28 cases reported in literature.

Esophagometer.

Dr. C. D. Spivak exhibited a device under the above name for measuring the length of the esophagus. It consists of a stomach tube, to the end of which is attached a whistle as long as the tube traverses the esophagus; blowing into the tube will produce no sound. As soon, however, as the whistle reaches the stomach, blowing into the tube will produce a whistling sound. The distance from the whistle to the incisor-teeth, minus the distance from the incisor-teeth to the uvula, will give the length of the esophagus.

Treatment of Typhoid Fever with Intra-Rectal Injection of Normal Salt Solution.

Dr. E. Stuver used cold normal salt solution by intrarectal injection in the recent epidemic in Fort Collins with excellent results. He uses a very cold solution, and when the fever is high, even ice-water.

Extra-Uterine Pregnancy.

Dr. O. J. Pfeiffer reported a case of extra-uterine pregnancy at the fimbriated end of the left tube, which recovered after the removal of the fetus. The fetus was only one-half inch long, although the pregnancy lasted two months. The sac is a remarkable symmetrical ovoidal sphere; its walls are about half an inch thick. The placental attachment is plainly shown.

An Outbreak of Pyemia, Suggesting Bubonic Plague.

Dr. J. N. Hall reported the histories of 13 cases which have occurred in Colorado during the early months of this year. If a single case occurs it would be called pyemia of cryptogenetic origin; if many such are seen, the name becomes a mockery. Of the 13 cases, 2 may be classed as multiple abscesses, with recovery; 3 proved fatal; 1 partial recovery, and 1 lost to sight. Four cases had enormous axillary abscesses, with unusual severity of constitutional symptoms; all recovered. One case had a single abscess, and several bed sores; it was fatal. All these cases were investigated by the State Board of Health, at the request of the attending physicians.

Pulmonary Tuberculosis in Grand Junction Indian School.

Dr. R. H. Bull reported 16 cases of tuberculosis that have occurred in the school since 1896, all of which improved as soon as they were returned to their respective reservations.

The Chest Pantograph.

Dr. C. B. Van Zant applied the pantograph—an instrument devised by Dr. W. S. Hall, of Chicago, for graphic recording of the contour of the chest—to the study of the following conditions: To accurately record the alterations in chest form, which are usually designated by the vague words "some depression," "deficient expansion," etc., progressive deformities of the chest following emphysema, pleurisy, fibroid phthisis, etc., congenital or unprogressive deformities like pigeon-breast, funnel breast, rachitis chest, and as a means of keeping track of many conditions beside those of the thorax, change of size and shape of face in acromegaly, of head in hydrocephalous, of neck in goiter, etc.

The X-Ray in Medicine, Surgery and Medical Jurisprudence.

Dr. G. H. Stover is of the opinion that skiagrams should not be introduced as evidence before a jury, because it is misleading; skiagrams never give an accurate image of the conditions as they actually exist; their meaning must be translated in connection with the findings of other and ordinary methods of examination.

The Physician in Relation to Dispensing of Medicine.

Dr. J. Tracy Melvin discussed the question whether we can be more certain in the results, more accurate in our dosage, more satisfactory to patients and ourselves by dispensing our remedies ourselves at the bedside than by sending our prescription to the pharmacist. In many of the country districts the physicians have been compelled by environment to adopt this plan, whether it is best or not, because of the long distance from any other source of supplies, but the question is: Should the practice be more general, and from choice, not necessity? He is in favor of the physician dispensing his own drugs, for the reasons that the drugs nowadays are put up in such a form that every physician can easily dispense them; the patient has more confidence in the remedy; the change in the drug does not attract attention, and the ability to change the dosage.

The Temperature, Pulse and Respiration in the Diagnosis and Prognosis of Certain Diseases of the Brain.

Dr. J. T. Eskridge, after a careful and exhaustive study of the subjects, makes the following conclusions: 1, a change in the character of respiration, rather than in its frequency, is sometimes one of the first symptoms of organic intra-cranial disease; 2, respiration, more frequent during sleep or unconsciousness, is strong evidence of organic disease of the brain; 3, apoplexy, due to hemorrhage, is attended with greater disturbances of the temperature of the body soon after the occurrence of the stroke than is the case when the apoplexy is due to thrombus or embolus. There will be a slight fall in the axillary temperature on the paralyzed side, and in 8 to 12 hours a slight rise on the same side; 4, in apoplexy, due to thrombus or embolus, there is no disturbance of temperature during the first two days; 5, if the temperature on the paralyzed side remains higher than on the opposite side for several weeks, it indicates softening or inflammation of the brain, and lends gravity to prognosis; 6, all cases of injuries to the head, in which the temperature does not reach normal or slightly above a few hours after the receipt of the trauma will likely prove fatal; 7, rapid, weak and intermittent or irregular pulse denotes great danger in traumatic cases; 8, an exceedingly slow (8 or 10 per minute) and intermittent respiration indicates a lesion at the base of the posterior fossa.

President's Address.

Dr. William P. Munn, the retiring President, in his annual address, referred to specialism, and said: There never was a greater field for the family physician than to-day. Specialism has its limitations, recognized only too well by those who practice the specialties. The specialists in cities the size of Denver we find overworked and under-paid specialists, who seek to right themselves by a return to general practice, either of surgery or medicine. The gynecologists now accept all kinds of surgery. The surgeons take obstetric and gynecologic cases. The lesson of all this is that specialism has its legitimate boundaries set by nature and the inherent condition of the people, and their customs; otherwise specialism can not survive.

CHICAGO PATHOLOGICAL SOCIETY.

Regular Meeting, held June 10, 1901.

President, Dr. L. Hektoen, in the chair.

Division of Nervous Cells.

Dr. Alice Hamilton presented a paper dealing with cell division in the central nervous system of the white rat before and after birth; the number and distribution of the mitoses, the period up to which they persist, and their character. Mitoses were found along the ventricular surfaces in the early stages of development, gradually ceasing here, and increasing in the outer layers, until at birth; almost all are in the outer layers. At birth mitoses are numerous and persist up to the end of the fourth day; beyond this period no examination was made. The dividing cells are of two kinds: 1, small, devoid of visible cell body, resembling cells of the neuroglia; 2, large, with abundant cytoplasm, round, pear-shaped or spindle-shaped. These are in the gray matter of the cord and brain and correspond in measurements with the multipolar and pyramidal cells.

In the later stages of development the offspring of the germinal cells become partially differentiated but without losing their power to divide. The large dividing cells are, then, immature nerve cells; the small are cells of the neuroglia. In the case of the white rat, these cells retain their power of division until after the fourth day of extra-uterine life.

Malignant Carbuncle of the Upper Lip, Followed by Pyemia.

Dr. W. B. Wherry related the following case: A barber, 23 years old, entered Prof. Bevan's service in the Presbyterian Hospital on Feb. 7, 1901, and died on Feb. 8, at 11:15 p. m.

About a week before his admission he extracted a "dead hair" from his upper lip. This was followed by redness of the lip and swelling, which rapidly extended to the side of the face and shoulder. He rapidly grew worse and died with all the characteristic symptoms of septico-pyemia. The post-mortem examination was held twelve hours after death by Professor Hektoen. The anatomical diagnosis is as follows: Acute, diffuse, purulent and necrotic staphylococcus inflammation of upper lip and adjacent parts of face; multiple abscesses and hemorrhagic pneumonic areas in lungs; double fibrinopurulent pleuritis; abscess in spleen; acute splenic swelling; cloudy swelling of kidneys and liver; persistent thymus.

Bacteriologically, a pure growth of the staphylococcus pyogenes aureus was isolated from the lip, heart's blood, pleural exudate, liver and spleen.

Histologically, the lip shows dense cellular infiltrations with foci of necrosis containing groups of cocci, which stain by Gram's method. The lung contains many pneumonic and hemorrhagic areas and mycotic emboli. The other organs show the characteristic changes of a severe infectious process. The dangers of this affection depend chiefly upon its location and the virulence of the infective agent; the prognosis is extremely grave on account of the liability to thrombosis and embolism. The treatment of the early stage, which has so far given the best results, is excision of the necrotic area and packing with iodoform gauze. After thrombosis and embolism have occurred, treatment at the present time seems to be hopeless.

The Distribution of Segmentation and Fragmentation in the Myocardium.

DR. W. B. WHERRY: Twenty hearts were carefully preserved and eighteen pieces were taken from each heart. In searching for changes, the divisions into simple segmentation, and degenerative fragmentation and segmentation, made by J. B. MacCallum, were kept in mind. Degenerative fragmentation and segmentation occurred twice in the left auricle. Segmentation was distributed in the following order of frequency: left papillary muscles, wall of left ventricle, right papillary muscles, posterior surface of apex, etc. The changes in the walls practically correspond to the changes in the papillary muscles.

"Diffuse" segmentation of both left papillary muscles, accompanied by diastasis and displacement of the segments, seems to indicate more or less general segmentation and fragmentation throughout the ventricles.

Cyst-Adenoma of Ovary.

DR. E. FRIEND: Patient 31 years old; married five years; never been pregnant; menstruation regular and painless; family history negative. About eight years ago severe pain developed in the region of the left ovary, but upon examination this was pronounced healthy. About one year ago a swelling appeared, extending from the symphysis pubis to the umbilicus, but this gave no pain until about a month ago. She then entered the hospital and at operation there was removed from the right ovary a small, multilocular cyst. The patient made an uninterrupted recovery and was discharged from the hospital yesterday.

Adenomas develop as a result of disturbance in the formation of Pflüger's tubes in the growing ovary. Cyst-adenomas are simply adenomas which have undergone cystic degeneration; they consist of long, round, tortuous cavities, separated from each other by connective tissue. These cavities may become obliterated entirely or partially by papilliform growths.

The present officers were re-elected for the coming year.

Medicolegal.

Validity of Law Requiring So Much Fat in Cream Sold.—The Supreme Court of Minnesota holds, in the case of State vs. the Crescent Creamery Company, that section 7002 of the General Statutes of Minnesota of 1894, which prohibits the sale of cream that contains less than 20 per centum of fat, is a valid exercise of the police power and constitutional. It says that there is undoubtedly less necessity for a statute to prevent deception in the sale of cream than there is of one to prevent fraud in the sale of milk, because the latter may be classed as a necessity, and the former as a luxury, and its sale not as general as that of milk; but the distinction is one of degree, not of principle. In either case, the legislature is the sole judge of the necessity and propriety of preventing deception in the sale of the article, by appropriate legislation. And the constitutionality of such a statute as the one in question rests upon the same principles as does the validity of statutes prohibiting the sale of milk unless it contains a prescribed percentage of fat and solids, and other similar statutes, the constitutionality of which has been uniformly sustained.

Evidence of Misrepresentation in Procuring License.—The issue in the case of Curryer vs. Oliver, brought by the secretary of the State Board of Medical Registration and Examination of Indiana, was whether a physician's license had been obtained by fraud and misrepresentation, the misrepresentation alleged being that the holder was a graduate of a reputable medical college, when in fact he was not a graduate of any medical college. The evidence consisted of the record kept in the office of the clerk of the Clay circuit court, showing the issuance of a license to the party under the act of 1885. The clerk who made the record testified that the license would not have been issued if the party had not made an affidavit, and that the information as to the name of the university from which he graduated and the date of his diploma were taken from such affidavit. The affidavit itself could not be found, although search was made in the proper place at various times. The book containing the copy of the license was identified as "The Record of Physicians' Certificates." It was kept in the clerk's office of Clay county. No objection was made to the admission in evidence of this record. The statute then provided, among other things, that "such applicant shall pay to such clerk for such license the sum of $1.50, and the clerk shall record such license, together with the name of the college in which such applicant graduated, and the date of his or her diploma, in a book to be kept for such purpose, and which shall be a public record." Upon this evidence there can be no doubt, the Appellate Court of Indiana holds, that the party procured a license upon the misrepresentation that he graduated from the institution named at the time named; at least, it says, such inference might be fairly drawn, the presumption, until the contrary is shown, being that the clerk properly discharged his duty. Moreover, there was introduced in evidence an affidavit made by this party in 1897 upon which a certificate of registration was issued to him in which affidavit it was stated by him that he was not a graduate of the university before referred to. And the court holds that from the evidence so introduced, in the absence of any explanation or denial by the party, the ultimate facts charged might have been properly inferred, wherefore it holds that it was error to sustain a motion for a finding and judgment in favor of the party on the evidence at the close of the petitioner's or secretary's evidence.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Tenia Solium (Tapeworm).

The treatment of tapeworm divides itself into three parts or stages: 1, the preparation of the intestinal canal; 2, the destruction of the tapeworm; 3, its expulsion. It must be remembered in carrying out the above treatment that it taxes the strength of the patient and consequently should not be undertaken on those patients recovering from prolonged illness, in sufferers from carcinoma, or tuberculosis or in pregnant women. To meet the first requirement, the intestine must be emptied as thoroughly as possible in order that the remedy may more readily come in contact with the parasite. Consequently a good laxative or mild cathartic should be given for a day or two previous to administering the teniafuge. At the same time, a diet should be prescribed consisting of fruit, containing small seeds such as strawberries, raspberries, gooseberries and new currants, also considerable milk, eggs and meat, with but little bread and potatoes. The night previous to the administration of the teniacide, the patient should partake of a salad consisting of dried herring, garlic and onions. The object, of course, in the above diet is to include only those articles that can be digested in the stomach. The above salad is supposed to be repulsive to the worm. A high enema should also be given the night previous to giving the teniafuge so as to cleanse thoroughly the large intestine.

To carry out the second part of the treatment some d

An Outbreak of Pyemia, Suggesting Bubonic Plague.

Dr. J. N. Hall reported the histories of 13 cases which have occurred in Colorado during the early months of this year. If a single case occurs it would be called pyemia of cryptogenetic origin; if many such are seen, the name becomes a mockery. Of the 13 cases, 2 may be classed as multiple abscesses, with recovery; 3 proved fatal; 1 partial recovery, and 1 lost to sight. Four cases had enormous axillary abscesses, with unusual severity of constitutional symptoms; all recovered. One case had a single abscess, and several bed sores; it was fatal. All these cases were investigated by the State Board of Health, at the request of the attending physicians.

Pulmonary Tuberculosis in Grand Junction Indian School.

Dr. R. H. Bull reported 16 cases of tuberculosis that have occurred in the school since 1896, all of which improved as soon as they were returned to their respective reservations.

The Chest Pantograph.

Dr. C. B. Van Zant applied the pantograph—an instrument devised by Dr. W. S. Hall, of Chicago, for graphic recording of the contour of the chest—to the study of the following conditions: To accurately record the alterations in chest form, which are usually designated by the vague words "some depression," "deficient expansion," etc., progressive deformities of the chest following emphysema, pleurisy, fibroid phthisis, etc., congenital or unprogressive deformities like pigeon-breast, funnel breast, rachitis chest, and as a means of keeping track of many conditions beside those of the thorax, change of size and shape of face in acromegaly, of head in hydrocephalous, of neck in goiter, etc.

The X-Ray in Medicine, Surgery and Medical Jurisprudence.

Dr. G. H. Stover is of the opinion that skiagrams should not be introduced as evidence before a jury, because it is misleading; skiagrams never give an accurate image of the conditions as they actually exist; their meaning must be translated in connection with the findings of other and ordinary methods of examination.

The Physician in Relation to Dispensing of Medicine.

Dr. J. Tracy Melvin discussed the question whether we can be more certain in the results, more accurate in our dosage, more satisfactory to patients and ourselves by dispensing our remedies ourselves at the bedside than by sending our prescription to the pharmacist. In many of the country districts the physicians have been compelled by environment to adopt this plan, whether it is best or not, because of the long distance from any other source of supplies, but the question is: Should the practice be more general, and from choice, not necessity? He is in favor of the physician dispensing his own drugs, for the reasons that the drugs nowadays are put up in such a form that every physician can easily dispense them; the patient has more confidence in the remedy; the change in the drug does not attract attention, and the ability to change the dosage.

The Temperature, Pulse and Respiration in the Diagnosis and Prognosis of Certain Diseases of the Brain.

Dr. J. T. Eskridge, after a careful and exhaustive study of the subjects, makes the following conclusions: 1, a change in the character of respiration, rather than in its frequency, is sometimes one of the first symptoms of organic intra-cranial disease; 2, respiration, more frequent during sleep or unconsciousness, is strong evidence of organic disease of the brain; 3, apoplexy, due to hemorrhage, is attended with greater disturbances of the temperature of the body soon after the occurrence of the stroke than is the case when the apoplexy is due to thrombus or embolus. There will be a slight fall in the axillary temperature on the paralyzed side, and in 8 to 12 hours a slight rise on the same side; 4, in apoplexy, due to thrombus or embolus, there is no disturbance of temperature during the first two days; 5, if the temperature on the paralyzed side remains higher than on the opposite side for several weeks, it indicates softening or inflammation of the brain, and lends gravity to prognosis; 6, all cases of injuries to the head, in which the temperature does not reach normal or slightly above a few hours after the receipt of the trauma will likely prove fatal; 7, rapid, weak and intermittent or irregular pulse denotes great danger in traumatic cases; 8, an exceedingly slow (8 or 10 per minute) and intermittent respiration indicates a lesion at the base of the posterior fossa.

President's Address.

Dr. William P. Munn, the retiring President, in his annual address, referred to specialism, and said: There never was a greater field for the family physician than to-day. Specialism has its limitations, recognized only too well by those who practice the specialties. The specialists in cities the size of Denver we find overworked and under-paid specialists, who seek to right themselves by a return to general practice, either of surgery or medicine. The gynecologists now accept all kinds of surgery. The surgeons take obstetric and gynecologic cases. The lesson of all this is that specialism has its legitimate boundaries set by nature and the inherent condition of the people, and their customs; otherwise specialism can not survive.

CHICAGO PATHOLOGICAL SOCIETY.

Regular Meeting, held June 10, 1901.

President, Dr. L. Hektoen, in the chair.

Division of Nervous Cells.

Dr. Alice Hamilton presented a paper dealing with cell division in the central nervous system of the white rat before and after birth; the number and distribution of the mitoses, the period up to which they persist, and their character. Mitoses were found along the ventricular surfaces in the early stages of development, gradually ceasing here, and increasing in the outer layers, until at birth; almost all are in the outer layers. At birth mitoses are numerous and persist up to the end of the fourth day; beyond this period no examination was made. The dividing cells are of two kinds: 1, small, devoid of visible cell body, resembling cells of the neuroglia; 2, large, with abundant cytoplasm, round, pear-shaped or spindle-shaped. These are in the gray matter of the cord and brain and correspond in measurements with the multipolar and pyramidal cells.

In the later stages of development the offspring of the germinal cells become partially differentiated but without losing their power to divide. The large dividing cells are, then, immature nerve cells; the small are cells of the neuroglia. In the case of the white rat, these cells retain their power of division until after the fourth day of extra-uterine life.

Malignant Carbuncle of the Upper Lip, Followed by Pyemia.

Dr. W. B. Wherry related the following case: A barber, 23 years old, entered Prof. Bevan's service in the Presbyterian Hospital on Feb. 7, 1901, and died on Feb. 8, at 11:15 p. m.

About a week before his admission he extracted a "dead hair" from his upper lip. This was followed by redness of the lip and swelling, which rapidly extended to the side of the face and shoulder. He rapidly grew worse and died with all the characteristic symptoms of septico-pyemia. The postmortem examination was held twelve hours after death by Professor Hektoen. The anatomical diagnosis is as follows: Acute, diffuse, purulent and necrotic staphylococcus inflammation of upper lip and adjacent parts of face; multiple abscesses and hemorrhagic pneumonic areas in lungs; double fibrinopurulent pleuritis; abscess in spleen; acute splenic swelling; cloudy swelling of kidneys and liver; persistent thymus.

Bacteriologically, a pure growth of the staphylococcus pyogenes aureus was isolated from the lip, heart's blood, pleural exudate, liver and spleen.

Histologically, the lip shows dense cellular infiltrations with foci of necrosis containing groups of cocci, which stain by Gram's method. The lung contains many pneumonic and hemorrhagic areas and mycotic emboli. The other organs show the characteristic changes of a severe infectious process. The dangers of this affection depend chiefly upon its location and the virulence of the infective agent; the prognosis is extremely grave on account of the liability to thrombosis and embolism. The treatment of the early stage, which has so far given the best results, is excision of the necrotic area and packing with iodoform gauze. After thrombosis and embolism have occurred, treatment at the present time seems to be hopeless.

The Distribution of Segmentation and Fragmentation in the Myocardium.

Dr. W. B. Wherry: Twenty hearts were carefully preserved and eighteen pieces were taken from each heart. In searching for changes, the divisions into simple segmentation, and degenerative fragmentation and segmentation, made by J. B. MacCallum, were kept in mind. Degenerative fragmentation and segmentation occurred twice in the left auricle. Segmentation was distributed in the following order of frequency: left papillary muscles, wall of left ventricle, right papillary muscles, posterior surface of apex, etc. The changes in the walls practically correspond to the changes in the papillary muscles.

"Diffuse" segmentation of both left papillary muscles, accompanied by diastasis and displacement of the segments, seems to indicate more or less general segmentation and fragmentation throughout the ventricles.

Cyst-Adenoma of Ovary.

Dr. E. Friend: Patient 31 years old; married five years; never been pregnant; menstruation regular and painless; family history negative. About eight years ago severe pain developed in the region of the left ovary, but upon examination this was pronounced healthy. About one year ago a swelling appeared, extending from the symphysis pubis to the umbilicus, but this gave no pain until about a month ago. She then entered the hospital and at operation there was removed from the right ovary a small, multilocular cyst. The patient made an uninterrupted recovery and was discharged from the hospital yesterday.

Adenomas develop as a result of disturbance in the formation of Pflüger's tubes in the growing ovary. Cyst-adenomas are simply adenomas which have undergone cystic degeneration; they consist of long, round, tortuous cavities, separated from each other by connective tissue. These cavities may become obliterated entirely or partially by papilliform growths.

The present officers were re-elected for the coming year.

Medicolegal.

Validity of Law Requiring So Much Fat in Cream Sold.—The Supreme Court of Minnesota holds, in the case of State vs. the Crescent Creamery Company, that section 7002 of the General Statutes of Minnesota of 1894, which prohibits the sale of cream that contains less than 20 per centum of fat, is a valid exercise of the police power and constitutional. It says that there is undoubtedly less necessity for a statute to prevent deception in the sale of cream than there is of one to prevent fraud in the sale of milk, because the latter may be classed as a necessity, and the former as a luxury, and its sale not as general as that of milk; but the distinction is one of degree, not of principle. In either case, the legislature is the sole judge of the necessity and propriety of preventing deception in the sale of the article, by appropriate legislation. And the constitutionality of such a statute as the one in question rests upon the same principles as does the validity of statutes prohibiting the sale of milk unless it contains a prescribed percentage of fat and solids, and other similar statutes, the constitutionality of which has been uniformly sustained.

Evidence of Misrepresentation in Procuring License.—The issue in the case of Curryer vs. Oliver, brought by the secretary of the State Board of Medical Registration and Examination of Indiana, was whether a physician's license had been obtained by fraud and misrepresentation, the misrepresentation alleged being that the holder was a graduate of a reputable medical college, when in fact he was not a graduate of any medical college. The evidence consisted of the record kept in the office of the clerk of the Clay circuit court, showing the issuance of a license to the party under the act of 1885. The clerk who made the record testified that the license would not have been issued if the party had not made an affidavit, and that the information as to the name of the university from which he graduated and the date of his diploma were taken from such affidavit. The affidavit itself could not be found, although search was made in the proper place at various times. The book containing the copy of the license was identified as "The Record of Physicians' Certificates." It was kept in the clerk's office of Clay county. No objection was made to the admission in evidence of this record. The statute then provided, among other things, that "such applicant shall pay to such clerk for such license the sum of $1.50, and the clerk shall record such license, together with the name of the college in which such applicant graduated, and the date of his or her diploma, in a book to be kept for such purpose, and which shall be a public record." Upon this evidence there can be no doubt, the Appellate Court of Indiana holds, that the party procured a license upon the misrepresentation that he graduated from the institution named at the time named; at least, it says, such inference might be fairly drawn, the presumption, until the contrary is shown, being that the clerk properly discharged his duty. Moreover, there was introduced in evidence an affidavit made by this party in 1897 upon which a certificate of registration was issued to him in which affidavit it was stated by him that he was not a graduate of the university before referred to. And the court holds that from the evidence so introduced, in the absence of any explanation or denial by the party, the ultimate facts charged might have been properly inferred, wherefore it holds that it was error to sustain a motion for a finding and judgment in favor of the party on the evidence at the close of the petitioner's or secretary's evidence.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Tenia Solium (Tapeworm).

The treatment of tapeworm divides itself into three parts or stages: 1, the preparation of the intestinal canal; 2, the destruction of the tapeworm; 3, its expulsion. It must be remembered in carrying out the above treatment that it taxes the strength of the patient and consequently should not be undertaken on those patients recovering from prolonged illness, in sufferers from carcinoma, or tuberculosis or in pregnant women. To meet the first requirement, the intestine must be emptied as thoroughly as possible in order that the remedy may more readily come in contact with the parasite. Consequently a good laxative or mild cathartic should be given for a day or two previous to administering the teniafuge. At the same time, a diet should be prescribed consisting of fruit, containing small seeds such as strawberries, raspberries, gooseberries and new currants, also considerable milk, eggs and meat, with but little bread and potatoes. The night previous to the administration of the teniacide, the patient should partake of a salad consisting of dried herring, garlic and onions. The object, of course, in the above diet is to include only those articles that can be digested in the stomach. The above salad is supposed to be repulsive to the worm. A high enema should also be given the night previous to giving the teniafuge so as to cleanse thoroughly the large intestine.

To carry out the second part of the treatment some drug must be administered that will either kill the worm or narcotize it so that it will release its hold upon the wall of the intestine and aid in its expulsion. There are a great many preparations recommended, but few of them are efficient. The one preparation most to be relied upon is the male fern, administered as follows:

℞.	Oleoresinæ aspidii	ʒi

M. Ft. capsulæ No. vi. Sig.: Take in keratin coated capsules at intervals of ten minutes, beginning early in the morning.

Previous to its administration the patient should be instructed to remain in bed in order to guard against vomiting. One hour after the last capsule has been taken, a brisk cathartic should be administered. Magnesium sulphate is regarded as preferable to oleum ricini, as the oil is said to increase the absorption of the male fern, which, of course, should be avoided on account of danger of producing toxic effects.

Treatment of the Umbilical Cord.

Dr. A. H. Longstreet, of Brooklyn, states in the *New York Med. Jour.*, that if there should be some inflammation or irritation of the umbilicus either before or after the cord drops, or if the parts keep moist, to apply the following:

℞.	Pulv. acidi salicylici	ʒi	4|
	Amyli	℥i	32|

M. *Bathe the part and dry thoroughly and apply as a dusting powder.*

Diarrhea in Children.

The following is recommended by Hirsch, in Pediatrics:

℞.	Argenti nitratis	gr. i	|06
	Sacchari albi	ʒii	8|
	Aq. destil.	℥ii	64|

M. Ft. mistura. Sig.: One teaspoonful every two hours for newly-weaned infants.

Treatment of Glaucoma.

Dr. Wicherkiewicz, as noted in *Med. Age*, recommends the following very highly in the treatment of acute as well as chronic glaucoma:

R.	Eserinæ salicylatis	gr. 1/6	|01
	Pilocarpinæ muriatis	gr. iii	|20
	Cocainæ muriatis	gr. i	|06
	Aq. destil.	ʒiiss	10|

M. Sig.: One drop into the affected eye once a day, at bedtime.

The mydriatic action of the cocain is neutralized in this combination through the eserin and pilocarpin, and intraocular tension is diminished through the use of this collyrium. He states that in fresh and acute cases, the solution should be dropped into the eyes three times a day.

In chronic glaucoma where iridectomies have no effect in stopping the progress of the disease, he has seen marked improvement in vision as well as in the structure of the eye, following the use of these drops, applied once a day at bedtime.

Amyl Nitrite in Seasickness.

The following prescription containing amyl nitrite is recommended by Martindale:

℞.	Amyl nitritis	m. viii	|5
	Alcoholis (90 per cent.)	ʒi	4|
	Pulv. trogacanthæ	gr. iv	|25
	Aquæ destil.	℥ii	64|

M. Sig.: One to two teaspoonfuls at one dose.

Treatment of Suppurative Otitis Media.

N. G. Ward, of Philadelphia, in an article published in *Amer. Med.*, states that in acute cases of otitis media, he syringes the ear out with a solution containing one to three drops of formalin to the ounce. In the most obstinate cases and those with granulations, alcohol is added:

℞.	Formalin	gtt. v	|30
	Alcoholis (95 per cent.)	ʒii	8|
	Aquæ q. s. ad	℥i	32|

M. Sig.: The affected ear to be irrigated with a syringe.

Santonin in Treatment of Tabetic Pains.

Negro, as stated in the *British Medical Journal*, has used santonin in relieving the lightning pains of tabes dorsalis with good success. He gave, at the beginning, 5 grains every three hours until three doses were given and in subsequent attacks he gave 10 grains at a dose. He continued this treatment during the crisis only and found that the pain would gradually disappear, and ceased entirely after the second dose was given.

Sodium Bicarbonate in Vomiting of Pregnancy.

Monin, as stated in *Lyon Médical*, notes the resemblance of the symptoms which pregnant women present to those of hypersecretion, such as gastric pain, nausea and vomiting, excessive acidity, occurring in the morning and relieved by taking food into the stomach. He believes in both cases that the stomach is secreting continuously and not at the digestive periods alone. He states that good results have been obtained by administering sodium bicarbonate in 30-grain doses four or five times a day in capsule.

Treatment of Mosquito Bites.

Dr. A. Manquat states that the most successful treatment consists in the local use of formalin, tincture of iodin and alcohol. He uses the pure formalin or alcohol in one-half strength. The tincture of iodin is objectionable because of *the stain it leaves on the skin.*

As a prophylactic against mosquito bites the following combination is of service:

℞.	Olei picis liq.		|
	Olei olivæ, āā	ʒvi	24|
	Olei hedeomæ (pennyroyal)	℥ss	16|
	Spts. camphoræ	ʒiii	12|
	Glycerini	ʒiiss	10|
	Acidi carbolici	ʒi	4|

M. Sig.: Apply on retiring.

Current Medical Literature.

bifurcation, with gangrene of the lower extremities. 6. Danger of rupture of sac from sudden withdrawal of abdominal support and displacement of adherent organs in the course of the exploratory laparotomy. 7. Danger of mistaking a fusiform for a sacciform aneurysm. 8. Danger from emboli and thrombi following incomplete coagulation of the blood in the sac (a very rare and practically unknown occurrence in abdominal cases). 9. Danger of shock. 10. Danger of sepsis. In the presence of this formidable array of dangers he asks what are the conditions favorable to its successful application, and answers that as theoretically possible but clinically rare the following conditions may be enumerated: 1, the aneurysm should be saccular; 2, it should be unilocular; 3, it should be provided with fairly strong, resisting walls; 4, the patient should be young or middle aged, fairly healthy, and free from general endarteritis and atheroma; 5, the aneurysmal orifice communicating the sac with the lumen of the parent artery should be small; 6, the aneurysmal sac should spring from the lower, inframesenteric division of the artery, preferably between the origin of the superior mesenteric and the bifurcation; 7, if given off from the celiac region the orifice should be situated on the posterior or lateral wall of the aorta. He says in conclusion, after analyzing the question from every point of view, we are compelled to admit that very little advantage is gained from the use of the method and he would restrict recommendation of the method to a small group of comparatively favorable cases in which the aneurysms are confined to the inframesenteric portion of the aorta and then only after other safer methods have been tried and failed. In aneurysms of the upper part of the aorta he would regard the procedure a pure experiment. He would not recommend it then, even in the danger of death, unless by the urgent solicitation of the patient and with a full explanation of the chances he has.

18. **Digitalis.**—Having had his attention called to a case of acute delirium and mania apparently due to the use of digitalis, Hall looked up the literature and finds the subject treated in a monograph by Duroziez, who reports twenty cases. He asks for the reports of the observations of the profession of similar facts.

21. **Right-Side Abdominal Surgery.**—Berg gives the histories, with diagnosis of appendicitis, of a case of typhoid fever with intestinal perforation and recovery after suturing, and a case of purulent tubercular peritonitis operated upon by celiotomy, with recovery; a case of empyema of the gall-bladder with impactions in the cystic duct, cholecystotomy and recovery; a case of suppurative appendicitis complicated with large ovarian cyst and pyosalpinx, abdominal section, removal of appendix, cyst and pus tubes, with recovery; a case of lymphosarcoma of the intestine simulating appendicitis, laparotomy, with recovery from operation. All these cases had been diagnosed as appendicitis and in all the symptoms pointed to trouble in the right iliac fossa. He remarks that these illustrate the difficulties that are and may be encountered in establishing a diagnosis in disease of the right side of the abdomen. Pain over the classic McBurney's point is not by any means always appendiceal in origin, and he suggests that when diagnosing appendicitis the other organs in the abdominal cavity ought to be examined.

22. **Tonometric Examination in Heart Disease.**—Schott's article dwells on the importance of an examination of the blood-pressure as a guide to the therapeutics of heart disease and illustrates from his own experience the use and value of the tonometer. While this is an instrument that may be dispensed with by the general practitioner, the physician who is desirous of making a minute and careful examination must use it. He says it may be considered a serious symptom whenever in any case undergoing the balneologic and gymnastic treatment the blood pressure is lowered. He has no hesitation in saying that when the tonometric figure as low as 65 or 60 mm. of mercury is found, therapy is of little avail and the bath and exercise treatment are both contraindicated. He believes that further careful experience with the Gaertner tonometer will fully confirm the statements and facts here given.

23. **Chronic Gonorrhea.**—The methods of treating chronic gonorrhea and post-gonorrheal urethritis are described by Valentine, who speaks particularly of certain points, such as the degree of dilatation and its duration, the need of asepsis, the question of involvement of the urethral adnexa, all the conditions that may tend to the chronicity of the gonococci, and the subject of marital reinfection. He offers the following conclusions: 1. That in these conditions, like all others, the cause of the perpetuation of the disease must be sought. 2. That no one remedy exists or can exist which will meet all the causative indications. 3. That the cause of a chronic urethral discharge is easily found, and when found can be successfully treated. 4. That the majority of chronic urethritides can be successfully treated by the general practitioner, and that the services of the specialist are required only in exceptional cases. 5. That the physician's duty is to warn all his patients of the dangers of gonorrhea to themselves, their family, and the public. 6. That no person who has had gonorrhea at any time should be allowed to marry until it is proven that he or she is free from the disease.

25. **Dietetic Treatment.**—The summary of Atwater and Benedict's article, concluded in this issue, shows that the four men under observation took a daily average of 154 grams of protein, 139 grams of fat, and 473 grams of carbohydrates, with a fuel value of 3925 calories daily per man. These figures correspond very closely with other observations of men under training and show that they take in their food about 50 per cent. more protein and 16 per cent. more energy than men at ordinary occupations in the United States whose dietaries have been studied. A comparison of the amount of nutriment in the food with those in the solid excreta shows the amounts actually available. These are nearly, but not quite the same, as the amount actually digested. It seems that the four athletes on an average digested their food just about as completely as the average man does. One notable feature of the experiment was found in the fact that the nitrogen excreted by the kidneys and intestines was considerably less in amount than the total nitrogen in the food. This means that there was considerable storage of nitrogen in the body, not far from 24 grams of protein per day, if no allowance is made for nitrogenous excretion in perspiration. Even after making a considerable allowance for excretion through the skin, it suggests the inquiry whether men who are storing nitrogen to such an extent are in the best physical condition and whether the amount of protein in the diet was the most appropriate for the purpose. The most important conclusion, however, to be derived from the experiments is, they say, that further and more detailed investigations are needed to show what diets are best for men under such muscular strain as that of oarsmen in training for races.

27. **Catharsis in Abdominal Surgery.**—The conclusions that seem to Crandon warranted from his study of the subject are: 1. In acute pelvic peritonitis both enemata and drugs by mouth should be used to produce catharsis before operation; drugs by mouth and oil enemata after operation. 2. In all acute inflammatory conditions of the abdomen where the alimentary tract is involved, the bowels should be moved by enemata alone, before and after operation, the enema of salts, turpentine and glycerin being the best.

30. **Pelvic Massage.**—After relating her experience with this method Southgate says: To sum up results obtained from my cases herein reported and others whose history I have not given you, pain and soreness in pelvis has been relieved; adhesions have been freed; exudates have been absorbed; large recent subinvolution was reduced; old chronically enlarged uteri have been rendered much smaller; enlarged fibrous ovaries have diminished slightly in size; retroverted, hypertrophied uteri, complicated with enlarged appendages and lax vaginal walls, reduced in size and retroversion somewhat improved; retroverted, prolapsed uterus without complications restored when electricity was added to the massage; severe dysmenorrhea of many years' standing, when caused by adherent ovary, cured.

31. **Rectal Valves.**—Mitchell reports a case where the existence of these valves was determined by proctoscopy, while the old methods had failed to reveal them.

38. **Surgery in Nervous Diseases.**—Pritchard doubts the value of surgery in functional nervous troubles and protests against the tendency of the surgeons to overstep their proper bounds in this direction. He concludes that in diseases of the brain, sinus phlebitis and traumatic hemorrhage, surgical procedure is not only legitimate, but is imperatively demanded. In brain tumors and in imbecility due to cranial deformity it has a legitimate field and while the results attained have not been specially gratifying, other remedial measures have resulted in no benefit whatever. Paralytic deformities, talipes, and contractions can be successfully treated by surgery alone. The loss of function may be completely relieved and useful action restored by muscle transplantation or section. Compression myelitis from trauma or other cause demands surgical treatment. Laminectomy is a legitimate procedure as demonstrated by results. In the treatment of neuroses, however, intrinsic or reflex, surgery is never a factor of any assured value. It may in exceptional cases prove a valuable adjuvant, but should never be relied upon alone. In non-reflex epilepsy the only excuse for surgical interference is that nothing else can be any worse. In reflex epilepsy and in other neuroses due to or aggravated by any ascertained reflex cause surgical removal of such reflex cause is legitimate, but the surgeon is wise who promises nothing. Among the sensory and motor neuroses surgery in the majority of instances seems a desperate experiment at best and often a crime. The domain of the surgeon in the treatment of epilepsy he believes is yet uncertain. Cautious, discriminating experimentation should constitute the guiding and dominant influence. While the ratio of failures to successes is large, he thinks that there is a future for surgery in this direction.

41. **Incudectomy.**—The mechanism in progressive hardness of hearing is given by Burnett, showing that the retraction of the incus is an important element and the operation of reducing the retractive force of the tensor tympani by incudectomy is recommended. The operation is made under general anesthesia and electric light with careful previous sterilization. When the membrane is intact the initial incision is made with a delicate knife, beginning close behind the short process of the malleus and following close behind the periphery backward and downward to a point below the line drawn horizontally through the umbo of the membrane. The flap thus made should be pushed inward toward the promontory by a probe armed with sterilized cotton. If there is no bleeding the incudostapedial joint is seen as soon as the flap of the membrane is pushed aside. If there be bleeding it must be mopped away. The incus being now in plain sight, it should be gently disarticulated from the stapes by drawing the former outward and downward by means of the incus hook-knife placed behind its long limb. Then the long limb of the incus should be grasped by special forceps and cautiously drawn down and outward into the auditory canal and then removed entirely from the ear. The operation is then finished. The meatus should be stopped with sterilized cotton and the ear let alone for twenty-four or forty-eight hours unless the meatus become moist with blood, when it should be changed. There should be no after-treatment in such cases. Sometimes slight reaction has occurred, but this is healed in a few days by simply mopping the ear with sterilized cotton and a solution of formalin (1 to 100), and he has never had any bad results. His experience with 78 cases has been good; the operation arrests and prevents progressive deafness and has a curative power in tinnitus and ear-vertigo.

51. **Intestinal Obstruction.**—The first duty in a case of intestinal obstruction is not to lose time in reaching a diagnosis or in instituting treatment. The essential phenomena are so striking to an observer as not to leave him long in doubt. In true ileus we have sudden and complete arrest of the fecal circulation indicated by sudden pain, vomiting, constipation, tympany, and stercoremia due to absorption through the paralyzed intestine, as shown by pale, drawn face, sunken eyes, a dark violet tinge to the skin, rapid, weak and small pulse, temperature normal at beginning, but later subnormal. The hopeless indication of these symptoms should be noted early, as the established conditions are unfavorable. Many physicians give cathartics, which Dunn condemns. Opium should not be given so as to mask the condition, though there is no other objection to its use. The most important thing where the obstruction is yet uncertain is the rational use of enteroclysis, using as much warm saline solution as possible with moderate pressure. This carefully conducted two or three times during the twenty-four or thirty-six hours will eliminate the existence of pseudo-ileus not requiring operation, and is not specially harmful in true ileus. The danger line for the patient should not be passed before operation is undertaken; ordinarily twenty-four to forty-eight hours should suffice. The various forms of internal strangulation should be watched for. These occur mostly in the middle third of life. Intussusception furnishes about one-third of the acute obstructions and usually occurs in patients under 10 years of age, and the discharge early of traces of blood in the stools is almost pathognomonic. Volvulus occurs in a large proportion of the cases of obstruction in the large intestines, hence, the diagnostic importance of inflation of the colon. In about 10 or 20 per cent. the nature and location of the obstruction remains more or less obscure to the best diagnostician, but the operator should not be very much embarrassed by this fact. Of the operations laparotomy is the one of choice, enterostomy being useful only in the last-resort cases. It is important that the operator should have everything at hand for any emergency and a definite system of handling pads, sponges, etc. Rapid work and the least possible rough handling of the intestine is important in advanced cases.

52. **Acute Nephritis.**—Head calls attention to definite types of symptoms of acute nephritis: 1. The gastrointestinal in which the attack is ushered in by vomiting, vomiting combined with diarrhea, or diarrhea alone. Over 50 per cent. of his 38 cases studied exhibit this type and he reports some of them as illustrations. 2. Next to this is the neurotic type, where the nervous system bears the brunt of the toxemia; the following symptoms occur; headache, sleeplessness, dyspnea, delirium, general or local convulsions and coma. About 28 per cent. of his cases were of this type. The two types just described are rarely seen associated. 3. This type is comprised of those cases characterized by the presence of edema, upon which so much stress has been laid by various writers. It is present in only 4 of his 38 cases. Edema is a much overestimated symptom of acute nephritis and has not the clinical importance attributed to it. Skin rashes are common enough as manifestations of nephritis to constitute the fourth type. In 3 cases of the 38 they were present, associated usually with edema. While as a rule striking symptoms are present, one sometimes meets with a case where there is no well-marked symptom to suggest the presence of the disease. This he calls the silent type of the disease, and he had about 5 of the 38 cases which he classed in this type. Other symptoms are enumerated, such as attacks of dizziness, abdominal pain, visual disturbances, epitaxis, etc.; these may occur but are not common and do not establish any special type of disease.

55. **Adrenalin.**—Todd reports a case in which adrenalin was injected to prevent hemorrhage in a case of operation for abscess in the neck, with the results that there was scarcely any bleeding, not enough to obscure the parts, though the patient in a previous operation had bled more than usual. The wound was packed with sterile gauze, but on removal from the neck this was unstained except where it had covered the cut surface, showing that there was no secondary hemorrhage. The adrenalin injections also had the effect of strengthening the heart, but otherwise there was no systemic disturbance.

56. **Tuberculosis.**—The object of Hunter's article is to call attention to a fundamental appearance of tubercular tissue not found anywhere else, viz., the presence of miliary tubercle. With this fact in mind one should not be left in doubt, he says,

in defining the tissue as to whether it is tubercular or cancerous.

58. **Psychotherapeutics.**—Patterson's article is an interesting historic résumé, and ends with a suggestion. He asks if the progress of the profession does not demand a judicious course in psychology as applied to the prevention, cause and cure of disease, to be added to the curriculum of medical instruction. Would it not be well to make a section of the state society (Michigan) devoted to the observation and study of the subject? Does not the dissemination of seeds of disease sent broadcast by mental suggestion in quack advertisements require local action for their prohibition?

72.—See abstract in The Journal of June 8, p. 1650.

75. **Ureteral Retrodisplacements.**—The operations for the various conditions are enumerated by Coggeshall as follows: 1. The Alexander operation unmodified when there is retroversion or retroflexion without adhesions so that the uterus is replaced with perfect ease; if the woman is still of child-bearing age; if the uterus is not markedly enlarged by actual hyperplasia, and if the symptoms confirmed by bimanual examination with or without ether, indicate nothing wrong with the adnexa and no evidences of fibroids. 2. The Goldspohn operation under the following conditions: Whenever in performing the Alexander, the ligament is broken or difficult to find, and also in a large number of retroversions where we can not be positive about the non-implication of the adnexa or where we know that diseased tubes or ovaries need to be dealt with or adhesions to be broken up, always provided that the adnexa are not too large to be brought out through the enlarged ring. 3. Posterior colpotomy followed by an Alexander seems more convenient than the last mentioned operation, when there is a large degree of retroflexion with adhesions, or of diseased adnexa, but are not too large to be brought out through the ordinary posterior vaginal incision, and are also markedly prolapsed. It is also the best operation in cases of retrocession as the most important measure for the cure of this form of retrodisplacements is the free division of the utero-sacral ligaments. 4. Where it is necessary for any purpose to open the abdomen by median incision, Gilliam's operation is the most convenient method of fastening the uterus in place except in cases where the round ligaments have undergone much atrophy. It has an advantage over doubling the ligaments on themselves, in throwing the thin distal portion of the ligament out of use, and depending upon the stronger proximal portion for support. It also changes their direction so that they pull more directly in the line required. 5. Where the round ligaments are not available, which hardly ever happens except in women past the menopause, ventral fixation may be employed. It is hardly ever the operation of choice, but one is sometimes driven to it by necessity. 6. Vaginal hysterectomy is in Coggeshall's opinion perfectly legitimate as a remedy for retroversion, especially with prolapse in women past the menopause, where there is marked atrophy of the vaginal wall, especially if there is any degree of ptosis of the abdominal organs generally. 7. The repair of lacerations of the cervix and perineum with the addition of anterior colporrhaphy where indicated, is a simple and effective means of treating moderate degrees of retroversion, especially accompanied with some prolapse in women who are not certainly past child-bearing or even in older women where neither atrophy of the deeper layers or vagina, nor enteroptosis is present. He does not believe that the present state of abdominal surgery has yet advanced to the point of so reducing the risk of opening the peritoneum to justify it where there is a very probable cure by a less serious operation.

78. **Myomectomy in Pregnancy.**—Emmet reports a case where nine myomata were removed during pregnancy without interfering with the processes and with labor and delivery at term. He thinks the lesson learned from this case is that hysterectomy may and should be avoided in all cases of myomata complicating pregnancy. If pregnancy were continued after so prolonged and irritating an operation as nine-fold myomectomy he can not see why myomectomy can not always be practiced with equally careful technique.

88. **Traumatic Epilepsy.**—Keen's article gives two cases of traumatic epilepsy operated upon, in one of which there appears to have been relief from operation. In the first there was a curious condition in which the cortex and white substance external to the posterior part of the lateral ventricle was entirely absent. The patient's mental condition before and afterwards was entirely normal. Whether the case was one of acquired porencephaly or whether there was simply destruction of the cerebral tissue between the ventricle and the dura at the time of the accident or by absorption later the author is unable to say.

89. **Pericardial Tuberculosis.**—The conclusions of Riesman are as follows: 1. Tuberculosis of the pericardium is comparatively common. 2. It may be primary in the clinical, rarely in the pathologic sense; it may be secondary. 3. The primary form is either a hematogenic infection or is the result of extension by contiguity from some trivial focus. 4. The most frequent source of infection is a tubercular mediastinal or bronchial lymph gland. 5. The primary form is usually chronic, and appears as an obliterative pericarditis. 6. In a large percentage of cases there is an associated mediastinitis, with adhesions to pleura, sternum, and ribs. 7. The symptoms are those of adherent pericarditis or mediastino-pericarditis. 8. In every case of obliterative pericarditis of obscure etiology tuberculosis should be suspected, particularly if there are no endocardial murmurs. 9. The diagnosis of tuberculosis of the pericardium can usually be made only by excluding other causes, except in rare instances of successful animal inoculation with fluid obtained by tapping a pleural cavity. 10. Tubercular pericarditis may not present any characteristic features at autopsy; hence, microscopical examinations should be made in every case of adherent pericardium before tuberculosis is excluded. 11. In rare cases a clinically primary tubercular pericarditis is acute, the exudate being serofibrinous, hemorrhagic, or purulent.

91.—See abstract in The Journal, xxxvi, p. 343.

92. **Gonorrheal Myositis.**—Ware reports a case of gonorrheal myositis with microscopic findings and discusses the literature, giving in brief the hitherto reported cases. He thinks that some permanent stiffening may eventuate in this case from the residue of connective tissue. He also is inclined to believe that the gonococcal myositis is an extension from similar inflammation of adjoining joints or the bones. The treatment is largely expectant and measures to relieve the pain, and when the acuity has abated massage. If the pain be excessive he thinks incision will often be of use.

95. **Progressive Muscular Dystrophy.**—Sachs and Brooks' paper reports a long-observed case with autopsy. They have specially investigated the spinal cord and find no evidences of tract disease. The occasional degenerated fibers in the posterior columns are probably ascending central branches of the degenerated spinal ganglion cells. The changes in the ganglion cells do not appear to them sufficient or of such a character as might be expected were the process a secondary one following long-standing muscular atrophy. They are inclined to consider them due to nutritional disturbances particularly affecting the mass of the cord following extensive and rapidly progressing curvature of that portion of the spinal column. The chief inference from the negative findings in this case is that there is not any evidence showing the disease of the muscles was due to disease of the gray or other portions of the spinal cord. Erb's theory should be regarded as purely speculative. At present there seems to be sufficient warrant to maintain distinction between the amyotrophies and the myopathies. It is difficult, however, to account for the latter group, unless we are satisfied simply to state that there must be some defect in the embryonal structure not permitting of satisfactory development of the muscular system. Two questions are raised: 1. Are all these cases of progressive dystrophy primarily muscular

disease or may not some of them be local expressions of universal lipomatosis? The case of a boy recently examined suggests apparently the latter possibility. 2. Are these muscular dystrophies necessarily progressive? The authors are inclined to offer a little hope from recent experiences. Two cases are reported in which there has been improvement at least.

108. **Two Unusual Surgical Cases.**—The cases reported are one of myoma with fibroid ovarian tumor, the first with only very obscure symptoms and the latter with none at all. The second case was one of ovariotomy in an extreme condition at the time of the operation.

116.—Ibid., p. 1105.

117.—Ibid., p. 1171.

122. **Diet and Nourishment.**—The assumption that modern culinary art and the average appetite are essentially wrong is held by Benedict to be more dangerous than acceptance of our habits of eating without question. As an illustration of this he notices the tendency to prescribe in typhoid a dietary which would be insufficient and intolerable in health, which is deficient in carbohydrates and iron, which is constipating, which is an excellent pabulum for the colon bacillus and undoubtedly for the typhoid bacillus also. It is deficient in chlorid and almost lacking in material to stimulate the appetite or the digestive secretion. If milk is unavailable the next most orthodox nutriment is animal broth rich in toxic extractives, with which the emunctories are already overcrowded. On the other hand, we are told that a cracker or a piece of bread or toast is apt to reach the ileum as solid food and inflict mechanical damage. While there is no question that the diet of typhoid should be limited as to frequency and amount we should remember that milk is more truly a solid food than most bread stuffs or cereals, and that it is possible to come somewhere near satisfying the patient's needs and his appetite without puncturing his bowel needlessly or creating a chemical disturbance that may lead to serious results. Others advise a diet of concentrated proteids with small amounts of food stuffs in gastric affections and a diet rich in fats and vegetables in intestinal disease; amylaceous dyspepsia, he thinks, is a bugbear rather over feared. Nearly all rigid dietaries neglect the need of the system for a large amount of glucose. Meats are served in too great abundance. In most digestive disorders he thinks it better to allow well-fried meat or boiled meat and rare roast beef. In all hyperchlorhydric cases salt is to be avoided and in the reverse condition it is indicated. To a large extent the individual appetite should be consulted and we should remember in the diet as to meat that most patients take too much. Most soft, starchy vegetables can be given in moderate amounts except in diabetic cases, though not the best food for fevers. Vegetables with hard seed coats should be avoided in gastric stagnation; bulky vegetables containing little nutriment and much cellulose should be avoided in nearly all cases coming under the physician's care. All foods except fruits, nuts and milk are better cooked than raw, and he would almost make an exception of milk. The worst sins of modern cooking are overseasoning and preparations of doughy masses. Cake, pastry, etc., should be withheld in sickness. Good ice cream is wholesome. Fruits and nuts are generally fairly aseptic and many absolutely antiseptic. Gelatin is a harmless basis for appetizing dishes and somewhat nourishing as a fuel food. One of the best desserts is candy, but it has lost much of its credit from the fact that it is eaten to excess between meals. Other foods would also produce bad results under similar treatment. If eaten regularly as a dessert at dinner probably few persons would care to eat more than 10 to 25 grams at once. As it is, it is not uncommon for a person to consume ten times this amount between two meals. Most persons coming under the physician's care need to be warned against tea and coffee; also chocolate usually is taken too strong. Water should be taken freely, with the ordinary diet at least a quart daily, allowing a glassful at each meal. It is better that water should be drunk between meals and in small quantities at a time. With gastric dilatation and atony no water should be taken at meals and one to two quarts be drunk in small quantities at intervals beginning one hour or so after a meal. Alcoholic liquors are seldom indicated, the milder malt liquors do more harm to the stomach and bile by causing fermentation; the strong liquors expend their energy rather on the nerve centers and glands. Alcohol should have no place in the dietary unless the patient has been so accustomed to it that it is deemed inexpedient to withdraw it immediately.

124. **Acetanilid.**—Earp calls attention to the popular indiscriminate use of acetanilid and its occasional dangers. Fifteen grains, he says, is considered the maximum dose, but he has seen harmful symptoms from one-half of this quantity. Some authors advise that 3 grains every hour may be given with safety. He has seen patients follow this rule and reach the danger line before 15 gr. had been given. Therefore, while the drug has its value and good results can be obtained, he wants to emphasize the fact that extreme caution should be observed in its use. It is probably never indicated when the patient is in an enfeebled condition, but often robust patients are just the ones that show its toxic effects. He has seen cases of poisoning in the use of 8 grains of acetanilid in individuals who had quite frequently used larger doses before. We have little knowledge of its deterioration, and the possibility of an impure product being sent out should be considered. It has been suggested that acetanilid may be to some extent mixed with acetoluid and sold as the genuine article. He has observed that people who are quiet during the time that several doses are taken are more likely to suffer from untoward effects than those who have taken it during vigorous exercise. If small doses are given and there is a decline in the temperature and signs of depression, a cardiac stimulant given early will overcome the unfavorable symptoms. Most of the cases of poisoning are those in which some person has purchased the drug and self-administered it. In the use of acetanilid he observes the following precautions: "Under no circumstances do I give it independent of other agents for the relief of pain; if used for this purpose, codein makes a good adjuvant and it should be guarded by some cardiac stimulant. In the general use of this remedy accidents occur, because intervals between the doses are too short and quite frequently the second dose is given when the first one has accomplished the desired result. I instruct the nurse in the physiological as well as in the therapeutic action, and the appropriate antidotal measures. Under these precautions this positive agent need not be abandoned, and favorable results may be obtained with a comparative degree of safety."

125. **Thiosinamin.**—This agent (chemically, allyl sulphocarbamid, allyl sulpho-urea, rhodalin), prepared from oil of mustard, is discussed by Robinson, who notices the literature and its various uses. It has been given by the mouth and in capsules in .5 to 3 grain doses and hypodermically in a 5 to 15 per cent. solution, doses varying from one to three or four grains. The injections are painful, but not excessively so. It is used in skin disorders, and he says: 1. The beneficial effects of thiosinamin in cicatrices, keloid, chronic glandular enlargements, and lupus are undoubted. 2. The drug seems to possess a beneficial influence in corneal opacities and in deafness due to sclerosis and adhesions. Further testimony is needed in this direction. 3. The drug is claimed to have given good results in urethral stricture and in gynecologic affections; but the number of reports is small and further evidence is necessary. 4. Taking into consideration the softening and resorbent effects of the drug, it seems rational to believe that it would produce good effects in such conditions as hypertrophied tonsils, hypertrophied turbinates, and in various hypertrophies of the skin. A cautious trial of the drug in the above conditions seems highly desirable. 5. From the latest reports it appears that when used locally—applied to or injected directly into the lesion—thiosinamin produces a stronger and more prompt impression than when administered internally.

Vegetables with hard seed coats should be avoided in gastric stagnation; bulky vegetables containing little nutriment and much cellulose should be avoided in nearly all cases coming under the physician's care. All foods except fruits, nuts and milk are better cooked than raw, and he would almost make an exception of milk. The worst sins of modern cooking are overseasoning and preparations of doughy masses. Cake, pastry, etc., should be withheld in sickness. Good ice cream is wholesome. Fruits and nuts are generally fairly aseptic and many absolutely antiseptic. Gelatin is a harmless basis for appetizing dishes and somewhat nourishing as a fuel food. One of the best desserts is candy, but it has lost much of its credit from the fact that it is eaten to excess between meals. Other foods would also produce bad results under similar treatment. If eaten regularly as a dessert at dinner probably few persons would care to eat more than 10 to 25 grams at once. As it is, it is not uncommon for a person to consume ten times this amount between two meals. Most persons coming under the physician's care need to be warned against tea and coffee; also chocolate usually is taken too strong. Water should be taken freely, with the ordinary diet at least a quart daily, allowing a glassful at each meal. It is better that water should be drunk between meals and in small quantities at a time. With gastric dilatation and atony no water should be taken at meals and one to two quarts be drunk in small quantities at intervals beginning one hour or so after a meal. Alcoholic liquors are seldom indicated, the milder malt liquors do more harm to the stomach and bile by causing fermentation; the strong liquors expend their energy rather on the nerve centers and glands. Alcohol should have no place in the dietary unless the patient has been so accustomed to it that it is deemed inexpedient to withdraw it immediately.

124. **Acetanilid.**—Earp calls attention to the popular indiscriminate use of acetanilid and its occasional dangers. Fifteen grains, he says, is considered the maximum dose, but he has seen harmful symptoms from one-half of this quantity. Some authors advise that 3 grains every hour may be given with safety. He has seen patients follow this rule and reach the danger line before 15 gr. had been given. Therefore, while the drug has its value and good results can be obtained, he wants to emphasize the fact that extreme caution should be observed in its use. It is probably never indicated when the patient is in an enfeebled condition, but often robust patients are just the ones that show its toxic effects. He has seen cases of poisoning in the use of 8 grains of acetanilid in individuals who had quite frequently used larger doses before. We have little knowledge of its deterioration, and the possibility of an impure product being sent out should be considered. It has been suggested that acetanilid may be to some extent mixed with acetolund and sold as the genuine article. He has observed that people who are quiet during the time that several doses are taken are more likely to suffer from untoward effects than those who have taken it during vigorous exercise. If small doses are given and there is a decline in the temperature and signs of depression, a cardiac stimulant given early will overcome the unfavorable symptoms. Most of the cases of poisoning are those in which some person has purchased the drug and self-administered it. In the use of acetanilid he observes the following precautions: "Under no circumstances do I give it independent of other agents for the relief of pain; if used for this purpose, codein makes a good adjuvant and it should be guarded by some cardiac stimulant. In the general use of this remedy accidents occur, because intervals between the doses are too short and quite frequently the second dose is given when the first one has accomplished the desired result. I instruct the nurse in the physiological as well as in the therapeutic action, and the appropriate antidotal measures. Under these precautions this positive agent need not be abandoned, and favorable results may be obtained with a comparative degree of safety.

125. **Thiosinamin.**—This agent (chemically, allyl sulphocarbamid, allyl sulpho-urea, rhodalin), prepared from oil of mustard, is discussed by Robinson, who notices the literature and its various uses. It has been given by the mouth and in capsules in .5 to 3 grain doses and hypodermically in a 5 to 15 per cent. solution, doses varying from one to three or four grains. The injections are painful, but not excessively so. It is used in skin disorders, and he says: 1. The beneficial effects of thiosinamin in cicatrices, keloid, chronic glandular enlargements, and lupus are undoubted. 2. The drug seems to possess a beneficial influence in corneal opacities and in deafness due to sclerosis and adhesions. Further testimony is needed in this direction. 3. The drug is claimed to have given good results in urethral stricture and in gynecologic affections; but the number of reports is small and further evidence is necessary. 4. Taking into consideration the softening and resorbent effects of the drug, it seems rational to believe that it would produce good effects in such conditions as hypertrophied tonsils, hypertrophied turbinates, and in various hypertrophies of the skin. A cautious trial of the drug in the above conditions seems highly desirable. 5. From the latest reports it appears that when used locally—applied to or injected directly into the lesion—thiosinamin produces a stronger and more prompt impression than when administered internally.

On the Agglutinating Property of Blood-Serum in Cases of Plague. D. LOUIS CAIRNS.—After noticing the results of investigation of the agglutinating power of serum in plague cases, and the method employed to obtain the emulsion, which is too full to be given here, Cairns gives tables of the cases tested by him in the recent Glasgow epidemic, from which the following deductions appear fully warranted: 1. During the early days of the disease the reaction is not manifested, and consequently in rapidly fatal cases is probably never obtained. 2. Agglutinating properties first appear in the blood towards the close of the first week of illness (dilution of 1 in 10) These gradually increase in intensity up to the sixth week of illness, and are sometimes maintained at a high level as late as the eighth week. After this date, however, in the majority of cases, a gradual decline in the agglutinative power of the serum becomes apparent. The rates of increase and decrease of the reaction, generally speaking, are approximately equal; occasionally, however, the reaction wanes and disappears in a shorter period than that occupied between its appearance and point of maximum intensity. 3. In very severe cases ultimately proving fatal the reaction, though present, never reaches a high degree of intensity. In cases of almost equal severity, however, in which an early and rapid convalescence followed, the reaction was of more marked character. 4. In the mildest forms of plague a high degree of agglutinating power is probably never attained and in some it appears to be absent. Striker, in fact, states that the reaction never appears in this class of cases, but this is undoubtedly too sweeping an assertion, as an undoubted and characteristic reaction in a dilution of 1 in 25 was obtained in two such cases. 5. The reaction, as a rule, is most marked in those severe cases characterized by an early and favorable crisis, and in such cases it disappears very slowly, having been shown to be present as late as the fifth month after the primary illness. He remarks on certain mild cases that, notwithstanding the indisposition, was slight and the temperature sometimes only normal, they are as important as the severer ones as regards the danger to the community. In the severer forms of disease the possibility of serum diagnosis is much greater, but the diagnostic value of this agglutinative reaction is most important during and subsequent to the stage of convalescence when the possibility of bacteriologic diagnosis is more or less remote. In all cases, moreover, where there are glandular enlargements of dubious nature during the presence of plague epidemic the appearance of this reaction can not fail to be of signal value.

Transplantation of Ureters into Rectum by an Extraperitoneal Method for Exstrophy of Bladder. GEORGE A. PETERS.—The case reported is that of a child aged 2 years and 7 months, suffering from ectopia vesicæ and procidentia recti. The procidentia was operated upon Dec. 7, 1896, incision being made in the median line above the imperfect umbilicus and consisted in making a longitudinal fold along the axis of the bowel, securing it by a double Lembert suture, thus narrowing its lumén and forming a fleshy column of the anterior fold of the rectum. This prevented the prolapse and recovery was satisfactory. The author reports it as a new operation and claims that it differs from any other in its essential features, consisting in narrowing the lumen of the lower dilated portion so as to make it practically impossible for the original apex of the protrusion to fall into it, and at the same time converting the part doubled in into a strong vertical fleshy column, the lower end of which is supported by the perineum, while the upper in turn supports the apex of the protrusion. He has operated since in another case also successfully. The exstrophy was treated also at another operation, nearly three years later. The sphincter was well stretched and the rectum previously cleared by a purge or enema of non-poisonous antiseptic solution. With the rectum blocked in its upper portion by a fair-sized sponge, a Jacques soft-rubber catheter, about No. 5 (English), was passed for about two inches into the ureter. The part containing the eye was cut off so that the urine entered the opening freely. A silk suture was then caught around the extreme end of the ureteral papilla, once or twice, and was also passed by a needle through the substance of the catheter so as to effectually prevent its slipping out, as it was the intention to retain these catheters in position at least forty-eight hours. Care was observed not to obstruct the lumen by passing the thread across it or by tying it too tightly. The distal end of the ureter with a goodly rosette of bladder muscle and mucous membrane was then dissected free, the catheter affording an excellent guide to its position. The idea was whatever virtue there might be in the peculiar termination of the ureter upon the inner surface of the bladder, should be retained when the transplantation was completed. As soon as the entire thickness of the bladder (here uncovered by peritoneum) had been snipped through with scissors, blunt dissection was employed and it was found not to be difficult to free the lower end of the ureter along the wall of the pelvis without injury to the peritoneum. Both of the ureters having been isolated, the whole of the bladder tissue was ablated from the perimeter where it merged into the skin, to the prostate where the vesiculæ seminales debouched. Great care was employed not to injure the peritoneum and in this case it caused no trouble. Next, the lateral aspects of the rectum, at a point below the reflection of the peritoneum, were exposed and the final step of the operation was the transplantation of the ureter into the lateral walls of the rectum, as follows: With a finger in the rectum the operator carefully determined the exact point where the implantation was to be made. It must be above the internal sphincter in the lateral and not in the anterior wall, to avoid kinking, and high enough to permit the ureter to project slightly, one-fourth or one-half inch, into the lumen of the bowel without stretching. As it is thus produced, it forms a papilla which, when pressed within the bowel, becomes converted into a valve, similar to that at the entrance of the bile duct and salivary ducts. This point having been decided upon, the operator or his assistant passes a slender forceps through the anus, presses them against it from the rectal aspect and lifts it across into the anterior wound. The wall of the bowel is now incised upon the projecting forceps, which are then forced gently through. By stretching and cutting, the wound is enlarged with great exactness, so as to exactly fit the ureter with its contained catheter and yet not squeeze them. The forceps are now opened, made to grasp the distal end of the catheter, and it is drawn into the bowel and out of the anus, the operator at the same time carefully directing the ureter through the slit and satisfying himself that its termination forms a papilla at least one-fourth of an inch long on the rectal mucous surface. In guiding the mouth of the ureter through the slit, the forceps may be passed back again beside the catheter and made to grasp the edge of the rosette of bladder tissue around the ureteral papilla. This process is repeated on the other side. The sponge plug is now withdrawn, care being taken not to disturb the catheters while so doing. No attempt was made to stitch the ureters in position. The catheters are left in position at least two or three days, or until they come away of themselves, which occurred in this case in about sixty hours. The author did not think it judicious to attempt any plastic operation for immediate closure of the abdominal wound. The whole area was surprisingly small and a moderately firm packing with iodoform gauze afforded efficient drainage and support. and acted as a splint to the ureters in their new position. Plastic closure may be done later when the implantation has healed securely and granulation been established. In this case the wound healed entirely by granulation and the scar was quite small and firm. It is now more than four years since the operation for procidentia recti was performed and about one and one-half years since the conversion of the rectum into the cloaca; the boy is in perfect health. There has not been the slightest tendency of return of the procidentia; there was no disturbance of function of the kidneys, and the mouths of the ureter could each be felt as a salient papilla as large as the tip of the little finger. There is no eczema or excoriation of anus or perineum, or any evidence that the rectum resents the presence of urine. The frequency of defecation depends largely upon the amount of fluid ingested, and the degree of activity of the boy. There is no evidence of reabsorption of urine from the rectum and the cloaca seems to act habitually as a bladder and only performs the defecation function at such times as a movement of the bowels should take place under normal conditions. For this extraperitoneal operation the following advantages are claimed: 1. There is absolutely no danger of peritonitis. 2. A prominent natural papilla is secured. This is the natural manner of debouchement of a duct upon a mucous surface, and affords the best possible protection against spread of infection up the ureters. 3. The ureters are further protected against infection or sloughing by lying undisturbed in their natural environment almost to the point of implantation. 4. The operation is easy of performance, and practically free from shock and exhaustion.

Annales de l'Institut Pasteur (Paris), May.

Endoglobular Hematozoa in Reptiles. P. L. Simond.—An endoglobular hematozoon of the hemameba species was found in a fresh-water turtle, and other species were discovered in crocodiles. They differ in their species in the same proportion as their hosts. It seems probable from the facts observed, that each given species of reptile has a certain single endoglobular parasite. Two cases of simultaneous infection by two parasites were noted in one instance, but it is possible that both parasites belonged to the same species and were merely in different stages of development.

Intracellular Digestion in the Sea Anemone. F. Mesnil.—A fish or crab taken in entire by the actinia or sea anemone, is destroyed by intracellular digestion. The digestive cell in these animals represents the embryonal stage of what, in the higher animals, constitutes two distinct systems—circulation and digestion. The arrangement of the digestive cells and their pseudopodic and plasmodial properties renders possible the paradoxical phenomenon of complete intracellular digestion.

Annales des Maladies des Org. Gen.-Urin. (Paris), May.

To Prevent Recurrence of Stones in the Bladder. Guyon.—The task of the surgeon in case of stone in the bladder is far from being restricted to the mere removal of the stone. The accompanying cystitis must be cured and the recurrence of stones prevented. Experience has demonstrated that the presence of calculi is no obstacle to the attenuation, and even the cure of a cystitis, if it is secondary; also, that the removal of the stones does not necessarily cure it. Local treatment is imperative both before and after the operation, especially when the cystitis is old and severe. Instillations are usually all that can be borne at first, followed by fractioned irrigations as soon as possible. Some cases allow the irrigations to be commenced from the start, followed by instillations. Calculi do not contraindicate a permanent sound. If the bladder is painful or hemorrhagic it may be necessary to evacuate the organ without leaving it empty, replacing each portion of urine withdrawn by the same amount of a tepid solution of boric acid. This topical treatment may relieve without anodynes, but sometimes a suppository or injection of an opium or antipyrin solution may be necessary. This treatment of the cystitis may require one or two weeks, the criteria being the number of mictions, the capacity of the bladder and the acidity of the urine. The urine becomes less infectious and it is possible to avoid febrile accidents. Silver nitrate is the best of all measures. It seems to have an elective action on pyogenic bacteria, and on the uri-bacillus liquefians, and is especially active when the urine ceases to be acid. Silver nitrate restores normal acidity to the urine, and this is the most certain means to prevent the recurrence of secondary calculi. Mineral substances become insoluble in an abnormal urine. Patients operated on should be cautioned not to neglect to test the reaction of their urine frequently with litmus paper, and resume the silver nitrate if the acidity is diminishing, and continue it until the urine turns the litmus paper red. This opposes a chemical barrier to the causes of the precipitation of the phosphates. General hygienic measures are of great importance, avoiding alcohol and rich food, alkaline water, and the tartrates of lime and magnesia, and a diet too abundant in vegetables. The patients should return once a week for repeated verification and successive evacuations.

Bulletin de la Soc. Med. des Hopitaux de Paris, May 30.

Gonorrheal Peritonitis in Little Girls. J. Comby.—In case of diffuse peritonitis in little girls, the external genitalia should always be carefully examined. If evidence of vulvovaginitis are discovered, this suggests the possibility of a gonorrheal origin. Comby had three cases under observation nearly at the same time, and was on the point of operating each, supposing that the diffuse peritonitis was the result of a perforating appendicitis, when the discovery of the gonorrheal lesions altered the diagnosis and with it the treatment. This form of peritonitis, in spite of its alarming onset, terminates in rapid recovery without surgical intervention.

Diagnosis of Nervous Affections from the Cerebrospinal Fluid. Babinski.—Examination of the cerebrospinal fluid in 120 persons resulted in finding the fluid normal in 60 cases, numbers of polynuclear cells in 1 case, and lymphocytes in great abundance in 56 cases, and scanty in 3. In the 56 persons who showed marked lymphocytosis, 50 were patients exhibiting symptoms which we associate with generalized syphilis—that is, tabes, general paralysis, Robertson's sign, isolated or accompanied by hemiplegia or paraplegia, or progressive muscular or pupil atrophy. In the remaining 6 cases there was some basis for the diagnosis of an affection of this kind, and it has developed since.

Intestinal Obstruction from Large Gall-Stone. Troisier.—An obese woman of 60, who had never had an attack of icterus, nor of hepatic colic, exhibited all the symptoms of acute intestinal obstruction for eight hours. Soon after, a gall-stone, measuring 7.5 cm. in circumference, was evacuated in the stools. It was 25 mm. thick and weighed 7 gm. dry. The size and the absence of icterus precluded the assumption of the passage of the stone through the bile duct. It must have entered the intestine through a cholecysto-duodenal fistula. No symptoms appeared during the three years since.

Echo Medical (Lille), May 26.

Sphenoidal Sinusitis. Gaudier.—A man applied for relief from an unbearable headache, which appeared every morning about 2 a. m., and lasted until about 5, when it ceased. The pain always started in the side of the right eye, ear and jaw, with subjective pulsation through the entire head. Two days before applying to Gaudier he had noticed a drop of pus when he blew his nose at 5 a. m., and the pains vanished about this time. He had no occasion to blow his nose nor expectorate at other times. In order to examine the sphenoidal sinus. the lumen of the meatus must be enlarged if necessary, and a droplet of pus will confirm the suspicion of sinusitis. Prompt cure follows the evacuation.

June 16.

The Country Physician in an Epidemic of Diphtheria. H. Delbecq.—The epidemic described was in a fishing hamlet where the lack of means and intelligence rendered local treatment impossible. Delbecq therefore renounced all attempts of the kind and relied solely upon serum treatment. All of the 19 cases recovered except 3, first seen in a moribund condition. The persons exposed, 65 in all, were injected with 5 to 10 c. c. as a preventive measure. The success of the serum treatment was remarkable. In one case a woman coughed up a perfect cast of the trachea and bronchi, to the fourth subdivision with seven ramifications on the left, and to the third with six ramifications on the right. The lumen of the tubular cast extended into the finest ramifications. The patient had been injected but once, receiving 20 c. c. of Roux's serum. Delbecq made a bacteriologic examination in 16 cases, placing the culture tube under the wing of a hen, with its feet tied together, in a box covered with a cloth, in order to maintain a constant temperature of 37 C. He did not order the school to be closed, but allowed it kept open after having the building disinfected, as he believed that the children, if allowed to play all the time, would be more liable to contract colds which would favor the evolution of diphtheria, than if they were kept regularly in school.

Journal de Medecine de Paris, June 9.

Role of the Lymphatic Glands in Infections and Diatheses. Courtois-Suffit.—Recent research, clinical and experimental, tends to establish that, from the physical, chemical and anatomic points of view, the lymphatic gland represents a true differentiated organ, intrusted with the task of defending the animal organism against both microbes and their toxins. It arrests the passage of bacteria and attenuates their virulence, while it is one of the places where the antitoxin is produced. The alterations in the glands are of two kinds: The first are manifestations of their functional activity, and are evidences of the struggle against the infection; the second are purely passive and are produced only secondarily, when the resistance of the ganglion has been overcome by the action of the infectious and toxic agents. A sound gland may, therefore, be hypertrophied from its excessive functional activity, or the increase in size may be due to infiltration with microbes or tuberculosis, or to cancerous degeneration. The simple hypertrophy of glands in the vicinity of a malignant neoplasm is a premalignant or paramalignant alteration. It is the reaction of the glands to the toxic products secreted by the neoplasm, and is for the purpose of producing unusual amounts of leucocytes, which pass into the lymph passages, and thence into the general circulation, explaining the leucocytosis observed in case of malignant disease. It precedes the appearance of specific cells in the ganglion. The glands in the vicinity of the neoplasm may also be infected by secondary pyogenic microbes or by tuberculosis. The relations between malignant disease and suppuration are well known, and the septic germs may be disseminated by the blood or lymph. Malignant disease passes through three phases—a local, a lymphatic, and a final, general circulation phase. According to Soupault and Labbe's latest statistics, the average number of cancerous *ganglia in* case of malignant disease of the mamma is 5, non-cancerous 2; of the stomach, liver and pancreas, cancerous 9, non-cancerous 5; of the peritoneum, cancerous 1, non-cancerous 2; of the tongue, cancerous 0, non-cancerous 4; of the tonsil, cancerous 4, non-cancerous 1; of the larynx and lungs, cancerous 2, non-cancerous 2; of the bladder and uterus, cancerous 0, non-cancerous 3. Youth favors metastases to the glands, owing to the greater activity of the lymphatic system during the first third of life. The nature of the tumor has also great influence on the early development and importance of secondary adenopathy. The participation of the glands in the cancerous process is more frequent and earlier in proportion as the tumor abounds more in epithelial cells and connective tissue is scanty. The remote adenopathy sometimes observed in case of malignant disease, usually affects the inguinal, axillary and supraclavicular glands. Tumefaction of the inguinal glands is too common for it to have any diagnostic value. The supraclavicular glands were affected in 21 out of 26 cases of malignant disease of the alimentary canal, and in 17 out of 37 cases of subdiaphragmatic visceral carcinoma. This frequently occurs also with carcinoma of the intestines, liver, kidneys, and suprarenal capsules.

June 16.

Action of Ozone on the Hemoglobin and Red Corpuscles. Oudin.—During the last twelve years Oudin has been making a special study of the influence of ozone on certain affections. He finds that it is unquestionably superior to all other therapeutic measures in its effect on the numbers and quality of the blood corpuscles. He describes three typical cases, showing the improvement obtained in six to eight weeks of ozone treatment. The first was a case of tuberculosis, with 7 per cent. oxyhemoglobin, 2,500,000 reds and weight 57 kilos. After six weeks of ozone treatment the proportion of oxyhemoglobin was 12 per cent., the number of reds 4,700,000, and the weight had increased by 5 kilos. The second case was that of a patient with chloroanemia, weighing 35 kilos, with 3,700,000 reds and 6 per cent. hemoglobin. After treatment the weight was 42 kilos, the number of reds 4,350,000, and the proportion of hemoglobin 10.5 per cent. The third patient was a victim of lead poisoning, with anemia and paralysis, weighing 50 kilos, with 5 per cent. oxyhemoglobin and 1,500,000 reds. *After two months of ozone treatment,* the weight had increased to 59 kilos, the reds to 5,200,000, and the proportion of oxyhemoglobin to 13 per cent. This effect on the oxyhemoglobin is perceptible even after the first inhalation.

Presse Medicale (Paris), June 15.

Therapeutic Puncture of the Sacral Canal—"The Epidural Method." F. Cathelin.—This new method of spinal injections is not meant for spinal cocainization only, but is advocated as a superior method of administering the majority of soluble medicines now administered by the mouth, rectum, or injected under the skin, or into a vein. The drug, in a weak solution, is introduced into the sacral canal and is thus brought at once into contact with the extensive plexus of veins which lines almost the entire bony structure. The absorption of the drug, therefore, proceeds simultaneously over a large surface, and its effect is felt to the remotest ramifications of the vascular system. For cocainization Cathelin injects on an average 4 cg. of a 1 per 100 or 200 solution of cocain. The method has already scored a number of brilliant successes in the palliative treatment of neuralgias in the legs, sciatica, lumbago, the fulgurant pains and gastric crises of tabes and also in intercostal neuralgia. It must also prove useful in cases of inoperable malignant disease of the rectum, of hemorrhoidal fissures, in painful delivery, and affections of the joints without effusion. It may be utilized for the administration of large doses of chloral in tetanus, or of the soluble mercurial salts, the benzoate or cyanid, for instance, in the severe cerebral or spinal form of tardy syphilis. The epidural injection is simpler and less dangerous than an intravenous injection, and never causes the local nodules, while its action is fully as effective, to say the least. The patient in the knee-chest position, the needle is inserted *obliquely between the lower tubercles of the sacrum, just* below the lowest median tubercle, where a triangular depression is evident. As the needle is introduced, it is slanted forward toward the anterior wall of the canal. There is a sensation as of forcing it through a taut membrane; when this is passed, the point of the needle is raised to follow the median line, and inserted for three to five centimeters, giving the sensation of passing through a soft substance. The fluid is then injected very slowly and the hole closed with a drop of collodion. The nerve roots are not affected by this procedure. The drug acts by osmosis through the extensive intraspinal venous network, which fills up the entire epidural space, as Cathelin has recently established by injecting colored wax and other substances under pressure.

June 19.

The Epidural Method. M. Brocard.—Sicard claims the *priority of this new method of spinal injections,* as he announced it at the meeting of the Société de Biologie, April 20, while Cathelin's communication was not presented until the *following week.* The three tubercles where the spinal canal is left exposed near the end of the sacrum, owing to the non-development of the laminæ and spinous processes, is the *point for the puncture, a little above the line uniting the* two tubercles. It can be approximately determined by measuring 7 cm. from the tip of the coccyx in the adult. The sacral *canal at this point has a transverse diameter of 15 to 18 mm.;* the antero-posterior diameter is 8 to 10 mm. The tip of the cone formed by the dura is 7 cm. above, out of reach of possible injury. The tolerance of the spinal canal outside the dura for non-toxic fluids is remarkably great, and experiments with stains injected in the cadaver showed that the fluid rapidly spreads through the entire epidural space in the dorsal and even cervical region. Cathelin's assumption that the drug acts by *absorption through the vast plexus of veins* in this space is probably correct, but there must be, besides this, some vasoconstriction phenomena, and also some effect on the nerve substance direct. *Chipault has the patient* assume the Trendelenburg position to facilitate the dissemination of the fluid, but Sicard prefers the lateral decubitus on the affected side, the legs flexed on the thighs drawn up to the pelvis, until the knees touch the chin.

The general direction of the puncture is that of the buttocks groove and Brocard and Chipault insert the needle for 4 to 5 cm. It hits against the coccyx if introduced too low, and against the roof of the sacral canal if too high, but in either case no damage is done. If the needle is held too upright it injures the periosteum of the floor. Nausea, fever, and headache never accompany this method of injection. The only symptoms observed were a sensation of heaviness in the limbs and very rarely formication, extending to the toes. Four or five hours after the injection a sensation as of a bruise is experienced in the lumbar region, gradually subsiding during the night. The analgesia obtained by spinal cocainization by this method never affected the skin, and it is, hence, exclusively medical analgesia. The relief of pain is immediate; it vanishes in two to five minutes after the introduction of the fluid. The analgesia obtained lasts for two or three days. The pain is then liable to reappear, but in the experiences to date, each recurrence is less violent and progressive improvement can thus be attained, amounting to actual cure. Colleville has cured three severe cases of sciatica by injecting a mixture of guaiacol 6 gm., orthoform .5 gm., and benzoic acid .365 gm. in almond oil q. s. to make 60 c. c. Chipault found the analgesia after cocainization by this method sufficient to allow resection of the coccyx.

The Cerebrospinal Fluid After Spinal Cocainization. Ravaut and Aubourg.—After spinal cocainization in Guinard's service, if the headache is intense a second puncture is made and a certain amount of cerebrospinal fluid allowed to escape. The relief is evident, and it was observed that whenever there was much headache the fluid spurted as if under high pressure, while it oozed a drop at a time when the headache was minimal. The turbidity of the fluid was also proportional to the amount of headache. The fluid of patients with severe headache contained large numbers of polynuclears, but a slight increase was noted in every case. Repeated lumbar puncture of the patients who exhibited most marked symptoms showed that the polynuclears gradually diminished in numbers and were replaced by lymphocytes and mononuclears, the fluid becoming normal again by the end of eight to twenty days. Repeated tests demonstrated that the meninges show no traces of the cocainization, resuming their normal condition in every respect after this interval. The reaction at first is evidently due to the direct toxic action of the cocain. Some of the patients were injected with the cocain dissolved in their own cerebrospinal fluid drawn just previous to the operation, but the symptoms were the same as when distilled water was the vehicle. The disappearance of all traces of the reaction testifies to the complete recuperation of the meninges and the ultimate harmlessness of spinal cocainization.

Deutsche Med. Wochenschrift (Berlin and Leipsic), June 20.

Treatment of Tuberculosis with Tuberculin. Goetsch.—It seems highly irrational to Goetsch to increase the fever with repeated injections of tuberculin when the patients are already febrile. He consequently never administers it when the patient has fever, and thus his patients are not exposed to the so-called dangers of tuberculin. He commences with very small doses and proceeds very slowly and cautiously, with the result that the nine patients thus treated during 1891 lost their bacilli and recovered their health. The three following years no patient was willing to take the tuberculin treatment owing to the general disfavor into which it had fallen. In 1895, however, tuberculous persons who had witnessed the complete recovery of his first nine patients, or been sent by them, applied for tuberculin treatment, and he was thus able to apply his principles on a large scale, the number of patients increasing each year, until he had 110 during 1900, a total of 224 in all. Of this number 37 are still under treatment, and of the remaining 175, 125 can be considered cured. The others were satisfied with the improvement attained, or for other reasons did not complete the cure. Tubercle bacilli were found in the sputum in 88 out of 224 who applied; 12 were rejected as being in too advanced stages of the disease. In 1 bacilli were discovered in suppurating cervical glands. The average length of treatment was 198 days, ranging from a minimum of 50 to 791. The average for patients with pulmonary tuberculosis was 143 days. The patients gained from 8 to 40 pounds in weight, averaging 19. Most of the cured cases return occasionally to allow oversight over their progress. A detailed record has been kept of each case, the weight, temperature morning, noon and evening, and the dose injected. The injections are made twice a week. During the first year Goetsch abstained from all adjuvants in order to test the tuberculin more thoroughly, but since convinced of its efficacy, he supplements it with the usual hygienic and other measures, but does not find that the course of treatment has been materially shortened thereby. As he never injects while the patient has fever, the temperature is reduced to normal by rest in bed and wet packs. If it is impossible to abolish the fever, tuberculin treatment is contra-indicated. No patient is submitted to this treatment whose case does not offer chances of success. Treatment is begun the third day, the dose corresponding to the general condition, usually .0001 gm. of old tuberculin. He has never succeeded in banishing the bacilli with the new tuberculin alone, although he has administered as much as 20 mg. at a time of T. R. in a number of cases. If this dose causes a febrile reaction, he reduces it by .00001 gm., and if this is not supported, he replaces the old by the new tuberculin, T. R., which is usually tolerated in the dose of .001 mg., and has proved its usefulness as a preliminary to the other. As soon as 1 mg. of T. R. is reached, then .0001 to .001 of old tuberculin is injected and tolerated without reaction. By gradually increasing the dose it is possible to raise it to 1 gm. of old tuberculin. The bacilli and cough have long disappeared by this time, the weight is normal, and the physical signs have subsided. But this result can be accomplished, Goetsch emphasizes, only by making it a principle never to increase the amount until the last dose was tolerated without a febrile reaction. He also, especially at the commencement of the treatment, insists that the patients must remain in bed forty-eight hours after the injection, to diminish the chances of a febrile reaction. The visible effect of the tuberculin in cutaneous tuberculosis is an intense redness and swelling of the affected points. In glandular tuberculosis the glands swell after each dose of the tuberculin, but subside again in two or three days. This same phenomenon is observed in affected tonsils, rendering their removal necessary in some cases. Patients with pulmonary tuberculosis frequently experience sensations as if a similar phenomenon were occurring in their lungs, and are able to locate the lesion. Hemoptysis seldom recurs and is less abundant. Fresh hemorrhages were never observed in any patient. The night sweats vanish during the third or fourth week of treatment. Four typical cases are described in full with nearly four pages of the tabulated temperature, dose, weight, and date, which it requires no knowledge of German to understand at a glance. The first is that of a teacher of 21, whose mother had died of tuberculosis: bacilli in sputum when admitted Jan. 4, 1898. He was dismissed cured April 4, with a gain of 34 pounds in weight and an additional gain of 15 pounds since. The first dose was .001 gm. and the last 1 gm. of old tuberculin. The temperature was occasionally 37.1 during the first twelve days. The second patient increased 21 pounds in weight during the treatment, which lasted five months. The table shows how the dose had to be frequently reduced as a febrile reaction occurred, the highest temperature being 38.8 C. These patients were examined recently by Professor Kast, who found them both perfectly sound. Koch supplements this communication by emphasizing the folly of administering tuberculin in cases of mixed infection, especially with suppurative processes. The specific action of the tuberculin is lost in such circumstances. He has always warned against too violent reaction, but, as he remarks, "Goetsch has gone beyond this and avoids any reaction at all, as far as possible, and yet he is able to reach very large doses. He has obtained remarkably good results by this method of procedure, as I recently convinced myself by a personal visit to his sanitarium. In order to incite other physicians to similar attempts he prepared the above communication for publication at my request."

[See editorial in last week's issue.]

Therapie der Gegenwart (Berlin), June.

A Cured Case of Aortic Insufficiency. H. Senator.—A cigarmaker, born in 1831, with a history of gonorrhea and syphilis at 20, was exhibited in clinics as a typical example of aortic insufficiency, in and after 1868, and the records contain several detailed descriptions of his symptoms, the classic picture of aortic insufficiency complicated by a tubercular lesion in one lung. Senator's astonishment may be imagined when, in 1871, he examined the man again to find not a single indication of aortic insufficiency, and the supposed tubercular focus in absolute *statu quo*. Repeated examinations convinced him that the valvular lesion must have healed, and that the tubercular focus must have been merely a syphilitic induration. The autopsy in April, 1901, confirmed this diagnosis. Only two semilunar valves were found at the orifice of the aorta, one evidently formed of two that had grown together. The valve was watertight. The pulmonary lesion was an induration with a patch of thickened pleura to correspond. Nothing was found to suggest an explanation of the fact observed during life that the systolic murmur had been loudest over the pulmonary orifice. The murmur must have originated at the orifice of the aorta in consequence of an eddy produced in the blood stream by the thickening and excrescences of the valves, but it was heard loudest over the pulmonary orifice for some inexplicable reason. The clinical records between 1877 and 1881 mentioned that the clinical picture had slightly altered. Two sounds were heard over the carotid, an indication that a diastolic sound was being developed at the aorta. Later it was noticed that two sounds were audible over the aorta, and that a murmur accompanied the second sound. Cured valvular lesions are rare and usually they are defects of the mitral valve, and always in young persons. In this case the man was 33 years old when it was first noted, and he survived thirty-seven years, living in poverty and never treated for the valvular affection. Treatment was always directed to the pulmonary lesion. No disturbances in compensation were noted at any time. His death was due to a circumscribed, comparatively recent tubercular lesion, causing hemoptysis. Senator was unable to find more than two cases of cured aortic insufficiency in the literature, in one the patient was 20, in the other, 37 years of age.

Treatment of Tetanus. E. Lexer.—Bergmann has lost confidence in serum treatment of tetanus and relies upon amputation as his chief support. Several fatal cases have been published recently in which all the conditions of early injection, etc., had been complied with. Lexer describes a case in which symptoms of tetanus appeared the sixth day after a compound fracture of the arm with an extensive phlegmon. Serum from Berne was injected into the veins and lateral ventricle, at the same time the arm was amputated close to the shoulder. The injections of serum were continued for several days, alternately subcutaneous, intravenous and cerebral. The temperature was continuously 40 C. An improvement for two days was followed by extremely severe symptoms, which gradually subsided in the course of two weeks and the patient had completely recovered by the end of four more.

Influence of Diet on Childbirth. W. Bokelmann.—In the *Centralblatt f. Gyn.*, 1889, 33, Prochownik recommended that women during the last few weeks of pregnancy confine themselves to antidiabetic diet, in order to check the development of fat in the fetus and render the bones more compressible. Bokelmann has followed these directions and proclaims, after an experience of eight years, that the advice is sound, and that women with contracted pelves, or who have previously given birth to exceptionally large children, or elderly primiparæ, are liable to derive the greatest benefit from this measure. Of course it is impossible to guarantee an easy birth in all cases, but the chances are decidedly in favor of it. He modifies Prochownik's directions to a certain extent, commencing the dieting gradually during the last third of the pregnancy and gradually growing stricter toward the last month. Water, soup, potatoes, sugar and beer are forbidden, although a moderate amount of carbonized water may be taken between meals. Sugar can be substituted by a small amount of saccharin. The woman may eat freely of meat, eggs, fish, green vegetables, cheese, a limited amount of bread, but butter *ad libitum*. As a beverage, 300 to 400 gm. of red or Mosel wine. The women usually feel so unusually well, subjectively, on this diet, that they bear its deprivations with pleasure. There are no unfavorable consequences for either mother or child. The children are certainly leaner, the bones of the head offer less resistance and artificial assistance is less frequently required. Another favorable effect is the more vigorous action of the uterine muscles; the diet is similar to that followed in the training of athletes, and it has a generally favorable action on the entire muscular system.

Oxygen in Therapeutics. F. Klemperer.—The benefits of the inhalation of oxygen are probably due to its direct action on the nerve centers. Michaelis has used about 150,000 liters of oxygen on his patients, and, with but one exception, has always noted a more or less marked subjective euphoria follow its use. The pulse and respiration become slower and more regular, and the same effect is observed in idiots and in comatose patients, excluding the effect of suggestion. Inhalations of oxygen have proved useful in intoxications and in dyspnea—it is an actual antidote to carbon dioxid—and, also, in intoxications from exhalations in mines and tunnels. It has been recommended for methemoglobin intoxication. Michaelis cured a case of morphin poisoning by this means; the patient being in profound coma and breathing only by artificial respiration. Spontaneous breathing followed the first inhalation of oxygen, and every time the respiration grew weak again, the oxygen restored it, strengthening the pulse and diminishing the cyanosis. Strychnin intoxication is also favorably affected by oxygen. After saturation of the blood with oxygen, it is impossible to induce convulsions in animals with strychnin or other reflex poisons. These inhalations have been advocated recently also for alcohol intoxication and in chloroform narcosis. Dyspnea is the second great indication for the inhalation of oxygen. Babinsky has reported the case of a girl of 13 suffocating from a piece of food in the trachea. The dyspnea and cyanosis were extreme, but the inhalation of oxygen raised the pulse and the lips became red. The transient restoration of circulation in such cases or with tracheal or laryngeal stenosis from compression by the thymus, may tide the patient past the danger point. The benefits of oxygen in bronchitis, emphysema and asthma are generally known, but in pneumonia or pleuritis, the compression or infiltration of the lung prevent the absorption of the oxygen. Cardiac asthma is favorably modified by the oxygen and likewise severe asthma caused by the compression of an aneurysm. Aside from intoxications and dyspnea, the benefits reported from the use of oxygen are probably due more or less to suggestion, as, for instance, the favorable effects in a few cases of chlorosis, nervous vomiting, the vomiting of pregnancy and uremic conditions. Anemia, leukemia and diabetes did not seem to be affected by the oxygen.

Calomel as a Diuretic. Klemperer.—On account of its marked diuretic properties, calomel is indicated in heart and lung affections and in dropsy, but for the same reason it is directly contraindicated in albuminuria and nephritis.

Therapeutic Inhalations on a Large Scale. Adam.—At the Flinsburg sanitarium the guests pass half an hour morning and evening in rooms in which the air is impregnated with salt solution, then with the essence of pine needles, and then with that of balsam fir, ten minutes in each. This is followed by a bath and a walk. The benefits are both local and general, and twenty years of experience have confirmed the efficacy of the inhalation of resinous fumes as a tonic measure. Adam suggests that shallow tanks filled with pine needles and fir twigs, with a stream of water trickling through them, on the principle of salt-evaporating pans, might prove a useful adjunct to city hospitals or spas.

Centralblatt f. Chirurgie (Leipsic), June 8.

Instrumental Application of Ligatures. M. Katzenstein.—In order to avoid all contact with the fingers in applying ligatures, Katzenstein has devised a set of instruments which apply a wire ring to the vessel and then crush it flat, thus mechanically occluding it. When he wishes to close the lumen of an intact vessel he applies an oval ring, 1, fig. 1, with a straight clasp in the center, like a buckle, which compresses the vessel firmly and completely. When a vessel has been severed, a ring is slipped over the stump and with a Péan forceps, the ring is crushed flat, thus holding the lumen tightly occluded, fig. 2. These rings are mounted in a grooved slide, fig. 3, with a spring, "c," and thumb-screw, "s," at one end, tapering at the other to fit into the jaws of the Péan forceps "a," which is provided with a spring on one side, "f" fig. 4, to hold the ring, "a," firmly until passed over the vessel stump, fig. 2. Open loops can be used instead of rings, with a suitable slide and the jaws of the Péan grooved to correspond to hold the loops. A year's experience with these instruments has confirmed their great value in asepsis and time-saving.

Amyl Nitrite as Antidote for Spinal Cocainization. A. Cordero.—This communication advocates the administration of amyl nitrite to diminish the disturbances due to cocain anesthesia by the lumbar route. The pallor and cold extremities of persons submitting to cocain anesthesia indicate that the drug has a pronounced vasoconstricting action. Amyl nitrite has a marked vasodilating effect and Cordero conceived the idea that the nitrite would counteract the vasoconstriction. Schilling some time ago suggested amyl nitrite as an antidote for cocain poisoning. After the injection of the cocain, the patients inhale three of four drops of amyl nitrite on a fold of gauze. The face becomes red, the pupils contract, and this condition of slight congestion of the head is kept up by administering a few more drops of the nitrite, if necessary, to a maximum of twenty. Twenty-seven patients thus treated escaped the usual after-effects of cocain; there was no severe vomiting nor violent headache. Nine were apyretic and the temperature rose to 38 C. in only two. There was slight nausea in a few cases, but all the patients were completely restored the next day with good appetite. Cordero considers himself justified in recommending this procedure as a reliable means of preventing the disagreeable consequences to which spinal cocainization is liable. He injects 6 to 9 mg. of cocain in a .5 per cent. warm solution, which he finds sufficient for all operations below the umbilicus.

Vratch (St. Petersburg), May 25.

Syphilitic Endocarditis. M. Y. Breitmann.—From his own observation and reviewing the literature on the subject, Breitmann is convinced that there is no such thing as a primary inflammation of the heart valves and proliferation, of exclusively syphilitic origin, in the condylomatous stage. Syphilitic alterations in the endocardium occur only in the tertiary stage, and are merely gummatous processes propagated from the myocardium. They can, however, simulate the clinical picture of a primary cardiac defect.

Genu Recurvatum. A. Worobjeff.—On the foundation of ten personal cases, which are described in detail, with several illustrations, Worobjeff classifies this condition as neurotic or osteopathic in origin. To the neurotic class belong the paralytic and arthropathic varieties and to the osteopathic the genu recurvatum resulting from a fracture or rhachitis, osteomyelitis, tuberculosis or syphilis. Determination of the cause is important both from the theoretical and practical point of view.

Auto-Amputation of the Appendix. P. D. Weingrow.—In a case of suppurative peri-appendicitis, the appendix became spontaneously amputated and was evacuated through the rectum eleven days after the onset of the acute infection. It occurred in the midst of robust health, the patient a man of 37.

Revista Medica de Bogota, Colombia, No. 251.

Analogy Between Yellow Fever and Snake-bite. N. Osorio.—The close resemblance between yellow fever and the symptoms that follow the bite of a venomous serpent suggests that the toxins in each may be identical. The anatomic lesions certainly seem to be identical in each. Especially remarkable in this respect is the degeneration of the liver cells, although it is much more rapid after a snake-bite than in yellow fever, in which the toxins have first to be elaborated, while in the snake-bite they are introduced *en masse*, already manufactured. Osorio thinks that researches in the line of reciprocal immunization with these toxins might lead to important results.

Books Received.

Surgical Experiences in South Africa, 1899-1900, Being Mainly a Clinical Study of the Nature and Effects of Injuries Produced by Bullets of Small Caliber. By George Henry Makins, F.R.C.S., Surgeon to St. Thomas' Hospital, London. Cloth. Pp. 493. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

Selected Researches in Pathology. By Alex. Gunn Auld, M.D., M.R.C.P., Author of "The Pathological History of Bronchial Affections, Pneumonia and *Fibroid Pneumonia*." With Illustrations. Cloth. Pp. 153. Price, $2.10 net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1901.

Diseases of the Thyroid Gland and Their Surgical Treatment. By James Berry, B.S., Lond., F.R.C.S., Surgeon to the Royal Free Hospital and Lecturer on Surgery at the London (Royal Free Hospital) School of Medicine for Women. Cloth. Pp. 367. Price, $4.00. Philadelphia: P. Blakiston's Son & Co. 1901.

Manuale di Chirurgia Operatoria. Dei Dottori R. Stecchi e A. Gardini. Con 118 Incisioni. Cloth. Pp. 321. Milano: Urico Hoepli. 1901.

Microbologia. Perche e Come Dorbiamo Diferderci dai Microbi, Malattie Infettive, Disinfeziono. Profilassi. Dott. Luciano Pizzini, Direttore del Laboratorio batteriologico del l'Ufficio d'Igiene di Bergamo. Cloth. Pp. 141. Milano: Ulrico Hoepli. 1901.

Igiene Della Bocca e dei Denti. Nozioni Elementari di Odontologia. Con 23 incisioni nel testo. Dott. Ludovico Couilliaux, Libero Docente di Odontoiatria nella R. Universita di Parma. Cloth. Pp. 298. Milano: Ulrico Hoepli. 1901.

Soccorsi D'Urgenza. Pel Dottore Carlo Calliano, Dirett. della Scuola Samaritana d'Italia alla Sede Centrale in Torino. Quinta Edizione Riveduta ed Ampliata, con 6 tavole illustrative. Cloth. Pp. 368. Milano: Ulrico Hoepli. 1901.

Manuale del Massaggio. Del Dottor Romolo Majnoni, Dirigente alla Poliambulanza di Milano gia Chirurgo Assistence al l'Instiuto dei Rachitici. Con 54 Incisioni. Cloth. Pp. 179. Milano: Ulrico Hoepli. 1901.

How to Cook for the Sick and Convalescent. Arranged for the Physician, Trained Nurse, and Home Use. By Helena V. Sachse, Graduate of the Philadelphia Cooking School. Cloth. Pp. 239. $1.00 net. Philadelphia: J. B. Lippincott Co. 1901.

Progressive Medicine, Vol. II, June, 1901. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in Jefferson Medical College of Philadelphia. Octavo, handsomely bound in cloth, 460 pages, with 81 engravings and one full-page plate. Issued quarterly. Price, $10.00 per year. Philadelphia and New York: Lea Brothers & Co.

Lectures on the History of Physiology During the Sixteenth, Seventeenth and Eighteenth Centuries. By Sir M. Foster, K.C.B., M.P., M.D., D.C.L., Sec. R.S., Professor of Physiology in the University of Cambridge. Cloth. Pp. 310. Price, $2.25. Cambridge: The University Press. 1901.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., June 20 to 26, 1901, inclusive:

John Carling, *major and surgeon, Vols., having tendered his* resignation, is honorably discharged from the service of the United States, to take effect July 3, 1901.

Charles M. Gandy, major and surgeon, U. S. A., former orders *modified so as to direct him to proceed to Manila, P. I., in the* transport *McClellan,* to sail from New York City, N. Y., July 10, 1901.

John H. Hess, dental surgeon, from Washington, D. C., to West Point, N. Y., for duty at the U. S. Military Academy.

Damaso T. Lainé, major and surgeon, Vols., recently appointed, relieved from duty in the Department of Cuba, to proceed to San Francisco, Cal., en route for service in the Division of the Philippines.

Appointments, promotions, and other changes in the regular and volunteer medical forces of the Army, reported from the Adjutant-General's Office, Washington, D. C., May 16 to June 15, 1901:

During the month ending June 15, 1901, the following promotions and other changes in the status of medical officers of the regular and volunteer forces were reported from the Adjutant-General's Office. Previous changes of this character were reported in the Journal of June 8, 1901.

Deaths, Regular Army.—Major Edward Everts, retired, May 17, 1901, at Alameda, Cal.; Major Louis S. Tesson, surgeon, June 17, 1901, at Vancouver Barracks, Wash.

Appointments, Volunteers.—To be surgeons, with the rank of major: Captain John Carling, assistant surgeon, U. S. Vols., May 11, 1901: Damaso T. Lainé, of Cuba, May 27, 1901; Abram L. Haines of New York, May 27, 1901; Captain Simon J. Fraser, assistant surgeon, U. S. Vols., May 31, 1901; Captain Howard A. Grube, assistant surgeon, U. S. Vols., May 31, 1901. To be assistant surgeons, with the rank of captain: Meyer Herman of Louisiana, May 11, 1901; John Bilbert of Pennsylvania, May 10, 1901.

Honorably Discharged, Volunteers.—Major B. Albert Liebermann, surgeon, 33d Infantry, May 27, 1901; Captain William C. Berlin, assistant surgeon, 45th Infantry, April 20, 1901.

Mustered Out with Regiments. Volunteers.—Major Harold L. Coffin, surgeon, 39th Infantry, May 10, 1901; First Lieutenant Charles Fitzpatrick, assistant surgeon, 45th Infantry, June 3, 1901.

Commissions Vacated by New Appointments.—Major James D. Glennan, surgeon, 38th Infantry, May 11, 1901, by appointment as major and surgeon, U. S. Vols.; Major William B. Banister, surgeon, Vols., April 2, 1901, by promotion to major and surgeon, U. S. A.; Major Samuel C. de Kraft, surgeon, Vols., May 10, 1901, by appointment as major and surgeon, Vols., under the act of February 2, 1901; Major William D. Bell, surgeon, 42d Infantry, May 18, 1901, by appointment as major and surgeon, U. S. Vols.; Captain Isaac W. Brewer, assistant surgeon, May 20, 1901, by appointment as major and surgeon, U. S. Vols.; Captain George P. Peed, assistant surgeon, May 15, 1901, by appointment as major and surgeon, U. S. Vols.; Captain John Carling, assistant surgeon, May 17, 1901, by appointment as major and surgeon, U. S. Vols.

Mustered Out of Service.—Major Charles F. Mason, surgeon, and Captain Richard S. Griswold, assistant surgeon, 26th Infantry, May 13, 1901; Major Charles L. G. Anderson, surgeon, and Captain Joseph L. Sanford, assistant surgeon, 29th Infantry, May 10, 1901; Major Frank E. Artand, surgeon, 45th Infantry, June 3, 1901; Major William Cogswill, surgeon, and Captain Henry H. Lee, assistant surgeon, 46th Infantry, May 31, 1901.

Navy Changes.

Changes in the Medical Corps of the Navy, week ended June 29, 1901:

P. A. Surgeon E. M. Shipp, detached from the *Michigan* and ordered to the Asiatic Station by vessel sailing from San Francisco, July 15.

P. A. Surgeon W. B. Grove, detached from the Naval Hospital, Norfolk, and ordered to the *Michigan,* June 28.

Assistant Surgeon G. C. Smith, detached from the *Vermont,* and ordered to temporary duty on the *Alvarado,* July 1.

Assistant Surgeon H. M. Tolfree, *ordered to the Vermont as the* relief of Assistant Surgeon G. C. Smith.

Assistant Surgeon J. S. Taylor, detached from the *Manila,* and ordered to the Naval Hospital, Yokohama, Japan.

Assistant *Surgeon* W. H. *Bucher, commissioned past assistant* surgeon, from April 15, 1901.

Drs. R. T. Atkinson and A. W. Balch appointed assistant surgeons in the Navy, from June 22, 1901.

P. A. Surgeon R. S. Blakeman, *ordered to the Naval Hospital,* Norfolk, Va.

Marine-Hospital Changes.

Official list of the changes of stations and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital service for the seven days ended June 27, 1901:

Banks, C. E., surgeon, granted leave of absence for two days.

Hastings, Hill, assistant surgeon, to proceed to San Diego, Cal., for special temporary duty.

Adams, E. B., acting assistant surgeon, granted leave of absence for three days from June 23, 1901, on account of sickness.

Bailey, C. W., acting assistant surgeon, granted leave of absence for ten days from June 21.

BOARD CONVENED.

Board convened to meet at Washington, D. C., June 27, 1901, for the physical examination of applicants for the position of engineer officer in the Revenue Cutter Service. Detail for the Board: Past Assistant Surgeon H. D. Gaddings, chairman; Past Assistant Surgeon J. B. Greene, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon General, U. S. Marine-Hospital Service, during the week ended June 29, 1901:

SMALLPOX—UNITED STATES.

California: Los Angeles, June 15-22, 1 case.
District of Columbia, Washington: June 15-22, 1 case.
Indiana: Evansville, June 22, 1 case.
Louisiana: New Orleans, June 15-22, 3 cases, 1 death.
Kentucky: Lexington, June 15-22, 1 case.
Massachusetts: Fall River, June 15-22, 6 cases; Fitchburg, June 1-8, 1 case; New Bedford, June 15-22, 1 death; Quincy, June 15-22, 1 case.
Michigan: Detroit, June 15-22, 2 cases; Grand Rapids, June 1-22, 8 cases.
Missouri: St. Louis, June 8-16, 34 cases.
Nebraska: Omaha, June 15-22, 5 cases.
New Hampshire: Manchester, June 15-22, 1 case.
New Jersey: Newark, June 15-22, 2 deaths; Jersey City, June 16-23, 2 cases.
New York: Buffalo, June 19, 1 case; Elmira, June 15-22, 1 case; New York, June 15-22, 60 cases; 20 deaths.
Ohio: Cincinnati, June 14-21, 4 cases; Cleveland, June 14-21, 24 cases.
Pennsylvania: Lebanon, June 15-22, 9 cases; Philadelphia, June 15-22, 2 cases.
Rhode Island: Providence, June 15-22, 1 death.
Tennessee: Memphis, June 14-21, 8 cases.
Utah: Salt Lake City, June 15-22, 2 cases.
West Virginia: Wheeling, June 15-22, 1 case.
Wisconsin: Green Bay, June 16-23, 1 case.

SMALLPOX—FOREIGN.

Canada: Stanbridge, June 6, present.
Columbia: Panama, June 10-17, 6 cases.
France: Paris, June 1-8, 24 deaths.
Germany: Hamburg, June 1-8, 2 cases.
Great Britain: Glasgow, June 7-14, 18 cases, 1 death; Liverpool, June 1-8, 1 case; London, June 1-8, 1 case.
Greece: Athens, June 1-8, 1 case.
India: Bombay, May 21-28, 8 deaths; Calcutta, May 18-25, 25 deaths; Karachi, May 19-26, 10 cases, 6 deaths.
Italy: Messina, June 1-8, 16 cases, 1 death.
Russia: St. Petersburg, May 24-June 1, 11 cases, 6 deaths; Warsaw, May 18-25, 7 deaths.
Spain: Corunna, June 1-8, 1 death.
Straits Settlements: Singapore, May 4-11, 1 death.

YELLOW FEVER.

Costa Rica: Port Limon, June 13, 1 case.

CHOLERA.

India: Bombay, May 21-28, 3 deaths; Calcutta, May 18-25, 65 deaths.

PLAGUE.

China: Hongkong, May 11-18, 122 cases, 113 deaths.
Egypt: Miniet, June 3, 2 cases; Zigazág, June 3, 1 case.
India: Bombay, May 21-28, 192 deaths; Calcutta, May 18-25, 47 deaths; Karachi, May 19-26, 112 cases, 107 deaths.
Japan: Formosa, May 21, 41 cases, 29 deaths.

Addresses.

ON THE ADVANCEMENT OF SURGICAL PEDIATRICS.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON DISEASES OF CHILDREN, AT THE FIFTY-SECOND ANNUAL MEETING OF THE A. M. A., AT ST. PAUL, MINN., JUNE 4-7, 1901.

SAMUEL W. KELLEY, M.D.
Professor of Diseases of Children in the Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University; Pediatrist to the Cleveland General Hospital, to the City Hospital, etc.
CLEVELAND, OHIO.

SURGERY IN PEDIATRICS.

I wish to offer some remarks on the advancement of the surgical side of pediatrics. Surgical pediatrics was later and slower in its development than was medical pediatrics. It is evident that the advance of such a science and art may be measured in many different ways. For instance: 1. By the recognition of the necessity and importance of it. 2. By the increase of actual knowledge concerning it—the discovery of new facts. 3. By the spread of knowledge through text-books and other literature, teaching in the medical schools, and in that kind of post-graduate schools wherein all are professors and all are pupils—namely, the medical societies. 4. By the extent to and the manner in which knowledge is applied in practice, both private and in hospitals, and the number and enthusiasm of those who devote themselves to it.

Obviously it will be impossible for me to trace elaborately the advance in this department, which would involve a complete history of the branch. I shall merely touch here and there certain salient points indicative of progress, or the lack of it.

Among all these indices one may usually measure very well the status of any department of learning by its own special literature; although it may happen that the facts or principles which should be combined into a science remain too long isolated or connected with various other groups, their own natural relationships unrecognized.

As we all know, numerous writers from the ancients down have alluded to the behavior of disease in children, the surgical, occasionally, as well as the medical; and yet as late as 1846, when Coley wrote an introduction to his "Practical Treatise on the Diseases of Children," he made the following statement: "I am not aware, however, that any author, British or foreign, has published a work comprehending all the diseases incident to children and their appropriate surgical as well as medical treatment. This omission may be accounted for by the division of the profession, which has limited the education and practice of physicians who have hitherto been the principal or only writers on infantile disorders."

This remark Dr. Coley makes after professing himself *acquainted among modern writers*, with the works of Astruc, Armstrong, Hamilton, Cheyne, Heberden, Becker, Plenk, Auvity, Burns, Capuron, Clarke, Gardien, Comet, Gölis, Dewees, Underwood, Billard, Meissner, Marley, Maunsell and Evanson, Barrier, Barthez and Rilliet, Rees, etc. I am ready to vouch that Dr. Coley's statement is well founded, for on perusal of many of the authors he mentions, and others not in his list, it becomes evident that none of them had given adequate attention to the surgical side of children's diseases.

Take for example Underwood—writing in 1795—who devoted 188 pages, or Part I, of his second volume, to " All such complaints as may fall under the province of the surgeon, with others that may be said to be of a mixed kind which," as he says, "should be all familiar to every accoucheur." But Underwood addressed his text as much to the laity as to the profession, and there is little or nothing in it to enlighten or guide the surgeon.

Even John Syer, surgeon, of London—who, being a surgeon, might be expected to do better in this respect —in his treatise, written in 1812, presented no topics which might be called surgical, excepting purulent ophthalmia, croup, and rickets. Under croup, he did not even mention any operative measures. However, tracheotomy, although known, was little esteemed until Trousseau's revival of it in 1850-57. As to rhachitis, Syer gave no definite account of the deformities and only a general description of deformity apparatus. For these, as for other diseases, he presented "the General Principles of their Domestic Treatment."

Dewees' "Treatise on the Physical and Medical Treatment of Children" (1826), included ophthalmia, croup, hip-disease, hydrocele, herniæ, and several skin affections, but even these few surgical topics can not be said to have been handled surgically.

Eberle's book (1833) had practically nothing surgical.

Billard—the English translation of whose work appeared in 1839—included in his treatise diseases of the skin, herniæ, prolapse of the rectum, intussusception (at least the kind found postmortem), malformations of various parts, and also fractures—*intra-uterine*, and of the new-born. But he pointed out no differences between those abnormalities and similar conditions in the adult, nor did he give the treatment for them. His attention was centered on "Recent Clinical Observation and Investigations in Pathological Anatomy," for this was the period of a new enthusiasm in that branch of medical science.

Evanson and Maunsell (1843) included syphilis, rhachitis, skin diseases, foreign bodies in the larynx, fractures, herniæ, nevi, tongue-tie, hare-lip, spina bifida, and ophthalmia, imperforate anus, and various deformities of the genito-urinary organs. Although they sometimes advised and described the treatment then considered appropriate for these difficulties, their general attitude seems to be expressed in a remark which appeared in connection with making an artificial anus in the groin (page 138), as follows:

"The operation would be a very hopeless one; but a consideration of its merits, and of the exact modes of performing the other operations, belong rather to the province of the surgeon, than of the child's physician—who, in that capacity, has merely to ascertain the nature of the deformity, and must draw upon his own general knowledge of surgery, or apply to another practitioner for the means of its removal." Their position on this point is again stated when treating of hare-lip (page 139). "The consideration and treatment of this deformity belongs to the surgeon—all that the child's physician, as such, has to do with it, is to consider *when* the operation should be performed. If the child can suck, it is better not to submit it to the hazards of an operation in early infancy. But cases occasionally occur in which such a degree of deformity exists as to demand immediate assistance in order to give the infant a chance for life. The nature of the operation, and modes of performing it, belong altogether to the province of surgery."

These authors mentioned are but examples. Others who might be cited—for instance, Stewart, 1843,—were much like them. So that it appears to be true that physicians had until then "been the principal or only writers upon infantile disorders," and had made little progress in surgical pediatrics.

But Coley purposed, as every good author should, to do better than his predecessors, and in the matter of the surgical diseases, he in some degree succeeded. He not only discoursed on the herniæ, imperforate anus, clubfoot and other distortions, hare-lip, laryngotomy and tracheotomy, foreign bodies swallowed or lodged in the pharynx, or in the vermiform appendix, prolapsus ani, pyothorax, vesical and urethral calculus, imperforate urethra and vagina, phimosis and paraphimosis, diseases of the joints, burns and scalds, spina bifida, and other surgical topics, but he advised and described the surgical treatment which experience or the literature up to his time had taught him. He also treated of diseases of the eyes, and of the skin, quite extensively. But Coley's book seems to have attracted little attention.

J. Forsyth Meigs, writing in 1848, presents nothing surgical, although his work more nearly equalled the quality of those on general medicine than had any upon diseases of children up to that time. Nor can the lectures of Charles West, the most admirable clinician and oft-quoted writer of his time, be said to deal with both sides of his subject.

In Churchill (1850), a few topics, as tracheotomy, paracentesis for pleurisy, hare-lip, cleft palate, imperforate anus, and spina bifida receive some surgical handling. Condie does not consider that surgical subjects fall within the scope of his treatise.

But by this time the knowledge of anatomy, of physiology, of pathology, and of the history of diseases and injuries had increased to such an extent, the observations of practical surgeons had so accumulated and the establishment of hospitals for children had so improved the facilities for the study of their diseases that their peculiarities and their importance could no longer be quite ignored by the profession.

About the year 1850, in Paris, while Trousseau taught the diseases of children, the surgical side was taught by Giraldes, who, however, published little in permanent form until later. In 1855, J. C. Forster, in London, had been making "A few remarks on the surgical diseases of children," and in 1860 his 8vo volume was published. It was also in the year 1860 that A. A. W. Johnson delivered, at the Hospital for Sick Children, a course of "Lectures on the Surgery of Childhood."

In 1863 we find that the council of the Medical Society of London, "recognizing the importance of this subject, have been led to believe that the interests of its members might be promoted and the profession benefited by having their attention drawn from the broad field of general medicine and surgery to the comparatively small one of the diseases of children; and on the strength of this belief have, abandoning the custom by which they have been hitherto bound, defined the subjects for the Lettsomian lectures"; and they nominated as lecturer, Mr. Thomas Bryant, who delivered three admirable lectures on the surgical diseases of children.

M. Giraldes, in Paris, had been followed as the leading teacher, by Guersant, whose "Notices sur la Chirurgie des Enfants," a series of very pointed and practical papers, found their way into an English translation in 1871. Giraldes prepared his clinical lectures for publication about the same time.

The work with both scalpel and pen, of the pioneers in this special line, had now become so valuable that still further interest was aroused and talent engaged in its behalf.

In 1869, Timothy Holmes issued his "Surgical Treatment of Children's Diseases," a book of nearly 700 pages, and in quality well worthy of its great author.

You will please observe that Holmes omitted, from the first edition, some special subjects, viz., diseases of the eye and ear, orthopedics and diseases of the skin, "not," he says, "because I am in favor of cutting up surgery into little pieces, but because the volume had already exceeded what I had intended; and these subjects are all excellently treated in works which are in everybody's hands." However, in the second edition—yielding to a sense of the fitness of things—he added a chapter on orthopedics. I mention this point in particular to illustrate the fact that the other specialties had advanced so much faster than pediatrics, and particularly than surgical pediatrics, as to have completely outstripped it in development as a distinct branch of our profession.

This statement is capable of verification by reference to the history of the other branches and is particularly shown by the specialties of the eye and ear, skin diseases and orthopedics, and later gynecology. *Obstetrics*, which synchronously with anatomy had become separated in the work of the medical schools from surgery, had remained in practice more distinctly in the hands of the general practitioners. But obstetrics, fecundated by its former companion, surgery, gave birth to a charming daughter, gynecology, who soon grew to maturity, came out in society with the greatest èclat, became the reigning belle and turned the heads of many susceptible young men for a long season. Thus gynecology, with the other specialties, chronologically took the lead of surgical pediatrics.

It is curious to observe in this connection that the "Compendium of Children's Diseases," of Johann Steiner, of Prague, which appeared about this same time, had for its English translator no less a personage than Lawson Tait, who added a few notes on the "Surgical Ailments of Children." One can not but speculate on what might have happened if Lawson Tait had felt a greater attraction for surgical pediatrics than for gynecology.

But my cursory sketch has brought me down to times almost within the recollection of the majority of my hearers. You are familiar with the record of the last thirty and the magnificent work of the last twenty years in the surgical diseases of children.

To continue a comparison among the recent achievements of those still active in professional life would require a nicer discrimination and might involve greater consequences than I care to assume; but I may at least mention, in passing, and almost at random, the names of Pooley, Marsh, Owen, St. Germain, Fumagalli, Willard, Wright, Ribiera y Sans, R. W. Parker, Charon and Gevaert, Karewski, McEwen, McClellan, Keen, Taylor, Wharton, Packard, Morris, Morton, Power, Phocas, and O'Dwyer, although I have omitted scores of worthy authors of books and writers of essays, brilliant investigators and able practitioners in this field. The new impulse came along with the grand impetus of general surgery occasioned by antisepticism.

There is now needed no elaborate argument to prove that there is a department of surgery as distinct from that of adult life as the medical diseases of children differ from those of their elders. As in medical pediatrics, so in surgical, we meet abnormalities found only in children, and also we meet those which, while they occur in adults as well as in children, are in the latter marked by different phenomena, manifest a different behavior, require a different treatment and often bring a different result from what would be usual in the same affections occurring in persons of mature years. It is only necessary to point out that the malformations, the early evidences of hereditary syphilis, separation of the epiphyses, croup, rickets, eneuresis, cancrum oris and noma, as well as certain herniæ and hydrocele and certain varieties of tumor, belong to the class of troubles found only in children. While intussusception, prolapse and polypus of the rectum, hip-joint disease, postnasal adenoids, enlarged tonsils, foreign bodies in the nose and ear, and cervical adenitis, although not exclusively found in children practically belong to the surgical affections of childhood.

Concerning the fractures and dislocations, empyema, and nearly the whole remaining list of surgical ailments —not to mention orthopedics or numerous affections of the eye and skin—we who have given the subject special study and are accustomed to surgical work among children know how common they are, and to a certain extent how different they are from similar afflictions in the adult. We are aware what peculiarities surround operative work upon children; how ill they bear hemorrhage or cold or prolonged shock, and how wonderfully they recuperate once the stress of the storm is past. The effects of anesthetics and of antiseptics, the art of dressing and bandaging and the use of medicines and diet in surgical cases—all these differ in children from similar cases in the grown up. Even if the specialists take all they dare there is enough remains of what might be called general surgery of children that is peculiar and requires special study and experience.

In view of all the splendid progress that has been made, it may appear ungrateful and hypercritical to seem dissatisfied; and yet to be satisfied is to stop progress, and there remains a great deal to be done to advance this department.

The exact points and degrees of difference in the phenomena of diseases and injuries, their prognosis and their treatment are not yet all completely mapped out, while there is much territory never yet thoroughly explored by any in the profession.

A larger amount of work needs to be done in the diffusion of such knowledge as is available, and in the application of it in practice; for the available knowledge is yet but indistinctly and vaguely seen in the minds of many practitioners of general medicine and surgery, and the all-around pediatrist as often finds the surgeon as the physician at fault in his work upon children, for want of special knowledge of them—mistaking the condition, miscalculating the probabilities, misjudging the vital force . In fact, the profession at large has not yet even sufficiently recognized the necessity and importance of this branch.

In the colleges insufficient attention is paid to the surgical diseases of children. In 1896, in an address as president of the Ohio State Pediatric Society, I gave the replies I had received to inquiries directed to the various medical colleges of the United States and Canada, upon the point whether surgical as well as medical diseases of children were taught in the regular course. Sixty-three colleges replied upon this subject. Thirty-seven of them said that the medical side only was taught and twenty-six taught surgical as well as medical pediatrics. When I asked the question, "Does the teacher individually consider that pediatrics includes the surgical as well as the medical diseases of children," I was answered affirmatively forty times, negatively, thirteen, while the remainder either left the question unanswered or answered indefinitely.

In the medical journals and in the medical societies one finds evidence that too little attention is paid to these surgical subjects. Examine your journals and the program of any medical society, even a pediatric society, and see what a small percentage of papers is on surgical topics in pediatrics. Some of those which should be found in the pediatric appear in the transactions of other specialties.

There is still in the minds of the profession, as of the people, a degree of misapprehension as to the natural and proper scope of pediatrics. There are many, both in and out of the profession, who look upon the child's doctor as a kind of a male nursemaid, who limits his practice to mixing milk and inspecting diapers. Very important things to be done are these, but scarcely the only work of a pediatrist!

There should, if necessary, be children's surgeons as well as children's physicians; or if, as Holmes says, one "objects to cutting up surgery into little pieces," it should at least be required that the surgeon extend his knowledge to diseases of children.

As to whether one man can practice, successfully, both medical and surgical pediatrics, is a question somewhat aside from our present theme. In my opinion the answer must depend on the circumstances and the man.

In addition to the misapprehension I have mentioned as to the scope of pediatrics, and to the fact that other specialties have outstripped it and to some extent taken from it, it is evident that the long-time-ago state of affairs yet prevails—namely that more physicians than surgeons have devoted themselves to this branch. To what extent this is a cause and to what extent an effect of the other causes, would be hard to decide. But I believe the present state of things will continue until earnest and devoted workers in this department succeed in gaining general recognition of its importance, and either more pediatrists turn their attention to surgery or more surgeons turn pediatrists.

My hope is that the attention of my hearers individually, and of the Section as an organization, may be aroused on this subject, and that you may be led to make further advancement in this beneficent and to me most delightful department of professional labor.

THE STUDY OF LARYNGOLOGY IN THE UNIVERSITY AND IN THE HIGHER MEDICAL EDUCATION.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON LARYNGOLOGY AND OTOLOGY, AT THE FIFTY-SECOND ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, AT ST. PAUL, MINN., JUNE 4-7, 1901.

JOHN N. MACKENZIE, M.D.
Clinical Professor of Laryngology and Rhinology in the Johns Hopkins University, and Laryngologist to the Johns Hopkins Hospital.
BALTIMORE, MD.

Instead of making the usual report on the year's progress in the specialty, I will depart from the prescribed routine and call attention to a subject which is of vital importance both to the laryngologist and to the profession at large. At the outset I wish it to be distinctly understood that I shall speak only of undergraduate instruction in schools of the very first rank, and not of the more elaborate training of the postgraduate for special work.

The study of laryngology has been grossly neglected in the medical schools of this country and Europe. It is either omitted entirely from the schedule of studies or, in many colleges at least, it is taught in a superficial, perfunctory sort of way that neither inspires faith in the instructor nor interest in the student.

Although the catalogue often tells in glowing terms of a course on laryngology, such a course will be found in practice to be like the "Co." in "A. Tetterby & Co.," "a mere poetical abstraction, altogether baseless and impersonal." In very few schools is it taken at all seriously, while in only one is it an obligatory study and a requisite for the degree. It seems to me, therefore, that the time is ripe for the discussion of its place in the university and in the higher medical education.

IMPORTANCE OF A STUDY OF LARYNGOLOGY AND ITS PROPER PLACE IN THE CURRICULUM.

I use the term laryngology in its broadest sense, to denote the anatomy, physiology and diseases of the upper respiratory apparatus, together with its connections and appendages, or accessory cavities. In this latter category may be placed the pharynx and the middle ear. The position assigned to laryngology in the university has been heretofore not at all commensurate with its importance, and yet of all the pure specialties, that is to say, those branches requiring special technique and special instruments and methods of precision, it is the most generally useful to the diagnostician and general practitioner. The time has gone by when it should be necessary to press the claims of laryngology to recognition of the highest rank. We no longer apologize—we demand. There was a time when laryngology meant little more than the art of laryngoscopy, and it was often prostituted to inferior use. It is no longer a simple method of examination and demonstration, but an enduring, vital force in medical progress, which lives and breathes and has its being within the very heart of inner medicine itself. It is no longer the Canaan of the quack, but a fair land of promise for the highest order of research. It should, therefore, hold high place in the curriculum of the college and university. It should have a separate, well-equipped department and a full professorship. While I do not wish to over-estimate the relative value of laryngology in a scheme of medical education, and while I am fully conscious of the present congested condition of the schedule, and the future necessity of a large number of elective studies, I am of the opinion that, in view of its very great importance, it should remain, as it is in the curriculum of the Johns Hopkins University, an obligatory study. If laryngology and ophthalmology should ever disappear from the list of compulsory studies, they should be the last to go. Their exile from a curriculm in which they have been once established would be, not an act of progress, but of retrogression.

THE FUTURE OF THE LARYNGOSCOPE.

A knowledge of the use of the laryngoscope will in the future be as necessary to the equipment of the advanced physician as is now a knowledge of the physical examination of the chest. It is absolutely invaluable to the diagnostician, for it is especially useful in the early detection of disease, often pointing, long in advance of classic signs and symptoms, the way to grave disorder. Time was, not very long ago, when physical diagnosis of the chest was not required of the medical student, and when the special knowledge of the art was supposed to be, and practically was, confined to the few. Now every practitioner of medicine knows, or thinks he knows, it all. The laryngoscope will go the way of the stethoscope and become the common property of the general practitioner of medicine. It will be an absolute necessity in that specialty which, next to surgery, is the highest of them all—the great special study of the future—internal medicine. The time will come when the art of laryngoscopy will be linked to general medicine as the art of physical diagnosis has become its inseparable associate.

INCREASING GENERAL KNOWLEDGE OF LARYNGOLOGY.

When, twenty-three years ago, the conception of creating the American Laryngological Association, the oldest special society of the kind in the world, arose in the brain of its too-early-lost founder, it was hardly possible to gather together more than a corporal's guard of men of national reputation in this department of medicine. Now the complexion of things has entirely changed. While at that time the specialist was found only in the larger cities, now there is scarcely a hamlet in the land that does not contain a laryngologist—indeed, in recent years the larynologist has, in some quarters at least, proliferated to an alarming extent.

There will come a time in the future—in the near future, perhaps—when the boundaries of the specialty will be almost indefinitely extended. The great advances which laryngology has made in recent years, the rapidly growing necessity of a knowledge of its special province in the elucidation of obscure conditions in adjacent and remote organs of the body, the popularity of its study and the accordingly rapidly increasing number and far-reaching geographic distribution of its votaries, will, in the course of time and in the nature of things, lead to such a congested state of the specialty that many will either be driven into the ranks of general medicine, or compelled to take up some other line of special work in connection with their original specialty. This already has been done in the smaller towns and in the great centers of population in the progressive west, where ophthalmology is the inseparable associate of laryngology and otology. The rational practice of the latter is impossible without a thorough knowledge of rhinology and diseases of the throat, and nothing is more illogical and grotesque than its solitary association with ophthalmology, except, perhaps, the combination alleged to have been practiced by a distinguished foreign ovariotomist, who took no cases except abdominal tumors and diseases of the ear.

While a more general knowledge of laryngology may have its drawbacks, if we look at the subject from a purely commercial point of view, it may have, among other things, a salutary effect in relegating to the rear that unfortunately numerically large element in our midst whose only claim to special knowledge resides in the possession of the necessary apparatus which goes to make up the armamentarium of a worker in this field.

DEVELOPMENT OF THE STUDY OF LARYNGOLOGY.

Let us now turn to the development of the study of laryngology by undergraduates in our medical schools, if, indeed, we may speak thus of a study which has practically just begun, and, in doing so, perhaps I can best illustrate the different phases of its development by giving a chapter from my own experience.

Twenty years ago, when I was on the working staff of the, then, largest throat and nose clinic in London—the Hospital in Golden Square—there was no place in that vast metropolis where the student could get systematic instruction in special work. None of the colleges or hospitals gave lectures on laryngology—nowhere was it requisite for the degree. All strangers in London, interested in the specialty, came to Golden Square, attracted there by the personality of Morell Mackenzie, then at the zenith of his popularity and power. With all the vast material at our command, there was practically no instruction given, except in the way of hasty demonstration of cases; and if the student or visitor learned anything, it was through close personal observation on his part and not through any gigantic effort to impart knowledge on the part of the medical staff. With one or two exceptions, the latter directed their attention almost solely to the larynx and thyroid gland, and the nasal passages were only examined when in quest of a polypus or when the attention was irresistibly attracted to these organs by the horrible stench of an ozena. The nasal cavities were practically neglected and the only apparatus in the hospital for the treatment of these diseases consisted of a pair of forceps for the removal of nasal polypi, and a hand-ball atomizer with a detergent solution for the treatment of ozena or any other miscellaneous disease of the nose that might irresistibly obtrude itself upon the recognition of the medical staff. When later I studied on the Continent, I found a like condition of affairs. In no school was laryngology taught to undergraduates, and the only means of acquiring special knowledge of the subject were the imperfect courses on diseases of the larynx given by the professors and their assistants. There was no special course in rhinology, which subject, as in England, was left entirely alone. I returned to my own country to find the same neglect of the study of laryngology that I had found in England and on the Continent.

In 1887 I was called to the chair of laryngology and rhinology in one of the oldest medical schools in America. The annual catalogue and circular told in flamboyant terms of a course on laryngology which at once set the mind to wondering how it would be possible for a student to escape from the institution without absorbing all that was coming and all that had gone before in that imperial domain. On my induction into office, I cast about me for the paraphernalia which should accompany my lofty position. I found in a dark closet or hole which led under the seats in the amphitheater where the lectures and clinics were given, a dilapidated lamp whose structure and general appearance of antiquity suggested the possibility that it might have been originally trimmed by some spirit in the age of fable, a broken laryngeal mirror, from whose back the quick-silver had long since departed and a cardboard diagram, colored blood red, like an eczema, which was supposed to represent the laryngeal image but looked more like a vulva on fire. These crude implements of the laryngoscopic art I found—and a tradition. According to this tradition my predecessor in office was accustomed to meet the class at the opening of each session, and, after a few introductory remarks, disappeared with a patient into the closet under the seats and closed its door. There was a period of breathless silence and intense expectation on the part of the students, during which time all manner of strange noises were heard in the darkness beneath them. These finally ceased, and the professor reappeared, his face radiant with satisfaction, and advancing toward the class, with the laryngeal mirror held aloft, triumphantly exclaimed, "Gentlemen, I have seen the vocal cords." According to the same tradition, that was all the laryngology the class got during the session.

The quarters assigned to me in the dispensary, where the patients were examined, consisted of a little compartment or "box" from which all sunlight and fresh air were carefully excluded, and in whose foul atmosphere two of my assistants subsequently probably contracted tuberculosis. It was thus thoroughly equipped and under such cheerful conditions that, without either moral or financial support on the part of the executive branch of the institution, I began the task of teaching practical laryngology to undergraduate students. Fortunately, I had excellent assistants, with whose aid I soon built up an excellent clinic, so that we were enabled to give the men during the session demonstrations of most of the diseases of the upper air-tract and all the common operations on the nose and throat. I gave the lectures and clinics and my assistants superintended the instruction of the students in the dispensary. Although attendance in the department of laryngology was not compulsory, and although no examination was ever held in this branch, the course was largely attended and many became so much interested in the subject that they subsequently took it up as a specialty.

In 1889 the Johns Hopkins Hospital threw open its doors, and several years later (1893) the medical school in connection with it and the University, was formally opened. The Johns Hopkins University deserves the credit of being the first institution of learning, either in this country or beyond the seas, to give to laryngology the prominence which its place in medical education demands. It was the first to make it an *obligatory* study in the curriculum, and to make an examination in this branch a requirement for the degree of Doctor of Medicine. This was one step, and in consideration of the former neglect of the subject, a prodigious one, to place laryngology where it properly belongs and to give to it the position and prestige to which it is justly entitled. It, therefore, marks an important era in the evolution of the undergraduate study of laryngology. If for no other reason, then, as a matter of historical interest, I will ask attention to the method of teaching the specialty which has been adopted in this institution. I shall content myself with simply giving a mere outline of the work, and shall not enter into matters of detail.

STUDY OF LARYNGOLOGY IN THE JOHNS HOPKINS MEDICAL SCHOOL.

The time required for the degree of Doctor of Medicine is four years, of nine months each. The requirements for entrance to the medical school are rigid, only those being admitted who give evidence of having had a liberal education as indicated by a collegiate degree in arts or science, including an acquaintance with Latin, a reading knowledge of French and German, and adequate training in physics, chemistry and biology. The first two years are devoted mainly to practical work of all kinds in the laboratories of anatomy, physiology, physiologic chemistry, pharmacology and toxicology, pathology and bacteriology. During the last two years much of the students' time is spent in practical work in the wards, laboratories and dispensary. It is not until the fourth year that the class enters the special departments. It is my intention to give a course on laryngology in the third year, so that when the student enters his graduating or fourth year course, he may be at least familiar with the use of the mirror. I mention these facts simply to show that, when the student reaches me, he is quite thoroughly trained, not only in the use of his brain, but also in the use of his hands. By constant practical work for three years, he has acquired an amount of manual dexterity which enables him to master the art of laryngoscopy with relative ease.

The graduating class is divided into four sections—each section (of the fourth-year class) attends for one and one-half hours daily during two months, the laryngological and rhinological department, where they receive practical instruction from my assistants and myself. After preliminary drilling in the use of the laryngoscope and other technical procedures, and in diagnosis, the student assumes the work of clinical assistant. He is given pathologic material for examination and diagnosis, and is encouraged to report cases and read papers before the Hospital Medical Society, to look up the literature of interesting subjects connected with laryngology, to observe for himself and, if he has time, to do original work. He is taught to investigate and to enquire, and I may say just here that it often requires a very high order of human ingenuity to construct an evasive answer to some of the conundrums with which I am frequently assailed. He takes his first lesson on the human subject—gets his first impression from Nature. I formerly used models; but some one stole them and I am glad they are gone.

By the above method, the teacher comes into direct personal contact with each member of the class, and is enabled to measure the mental status of the individual. In no other way can laryngology be properly taught. It is hard work, but it pays in the results which are accomplished. Laryngology can not be taught by text-book or lecture. It must be taught over the shoulder of the instructor, and on the part of the student, must be acquired by direct contact with, and personal observation on, the living subject.

While the didactic lecture is fast becoming an anachronism, I do not believe that the day of its usefulness is completely gone. I give a systematic course of weekly lectures to the entire class, which are supplemented by pathologic and clinical demonstrations, on the anatomy, physiology and commoner diseases of the upper air-passages and their relations to morbid processes in other parts of the body. In this course especial attention is paid to diagnosis. The object of these lectures is two-fold: 1, to give in a concentrated form and in the shortest possible time information which could not be acquired except by great additional labor on the part of the student, and 2, to avoid endless repetition in the section room.

In the matter of text-books and literature, the class is shown the principal works and current periodicals in English, French and German. No special text-book is recommended or required; but, in connection with the lectures, the students are referred to special articles and monographs containing the classic literature of each special subject.

The question of the value of examinations is a very important one and one which is destined soon to be pressed to final settlement. While I can not go as far as my gifted friend and colleague, Professor Mall,[1] who is of the opinion that it would be well to separate them from the course of instruction entirely, I must confess that I am very much in sympathy with him in the main points of his contention. But until a more rational and exact method of accomplishing the same results be devised, I am afraid the examination must remain as a necessary evil. It is often a farce. One of the best examination papers I ever received was from a student who, on account of a serious illness, was compelled to absent himself from the very lectures on which the class was being examined. He had used the notes of a fellow-student and came back at me almost with my own words. In the university in which I received my first medical degree, instruction, except in the department of anatomy, which was practically and ably taught, was entirely by didactic lectures. We sat all day in the lecture-room taking notes, and spent the entire evening "cramming" them for the next recitation. We never saw a medical case. Once during the session, the professor of surgery brought in the colored janitor, stripped him and bandaged his legs and arms. This was our only course in practical surgery. Those were the good old days when, as Mall says, the students "heard much, saw little and did nothing." When the day of examination arrived I knew my text and note books from cover to cover, and could locate with unerring accuracy any required item of information to the page and to the line. My memory was so saturated with medical lore that it took me some years after I left college to forget it. I was invincible in the examination room, but helpless at the bedside.

The best examination is the observation of the student in his daily work and the resulting estimate of his personal equation. During the first two years I gave an oral examination at the end of the term, carrying each student over the entire field covered by the lectures, but, as the size of the class increased, this had to be abandoned, and I now give a single written examination, of which the following, which was my first, is an example.

1. Give the physiology of the nasal and accessory cavities.
2. General symptoms and diagnostic signs of suppuration in the nasal accessory cavities—diagnosis of pus in the antrum *maxillare*.
3. Early laryngoscopic diagnosis of tuberculosis and cancer: characteristics of syphilitic, cancerous and tubercular ulceration in the upper air-passages.

---

[1] Liberty in Medical Education; Phila. Med. Jour., April 1, 1899.

4. Chief causes, symptoms and laryngoscopic signs of double, complete abductor paralysis.

5. Nature and diagnosis of so-called nasal reflex neuroses.

Out of a class of thirty-four there were only two who failed to pass.

This, in brief, is a simple outline of the way in which laryngology is taught in the Johns Hopkins Medical School. I am fully aware of the imperfections of the method; but everything must have a beginning, and time and further experience will doubtless make it more perfect. In the classes under my care it has so far been very successful. The net result is that when the student graduates he has made a very fair groundwork on which to base, in the future, if he will, a more elaborate study of the specialty.

LARYNGOLOGY THE INSEPARABLE ASSOCIATE OF GENERAL MEDICINE.

In teaching laryngology the instructor should forever bear in mind, and the student should never be allowed to lose sight of, the fact that it is an inseparable part of general medicine—that the pathology of nasal and laryngeal diseases is not an isolated pathology; that the appearance of disease in the upper air-tract is governed by the laws that condition the development and course of disease in general, and that the rational interpretation of these affections presupposes, therefore, the application of general pathologic principles to the peculiar conditions which the anatomic and physiologic functions of the structures involve. Above all, he should remember that peculiarity of structure is not anatomic isolation; he should remember the correlation of organ and organ, the sympathy of tissue and tissue which makes up the perfect physiologic life of man. In looking upon the subject from the high vantage ground of general pathology and laws of health, the student is in a better position to apprehend the rôle which external and internal influences play in the evolution of disease of the respiratory apparatus, than if he viewed the subject from the level of a narrow specialism or from the standpoint of the mere empiric.

FRATERNITY AND CO-OPERATION AMONG THE DIFFERENT DEPARTMENTS OF MEDICINE.

Laryngology should not be studied apart, but kept in constant and closest contact with all the other departments of the university. Let there be more fraternity among the different specialties—more co-operation. If special workers in the different departments of medicine would, instead of holding aloof from each other, combine the special knowledge they possess in a common endeavor to elucidate the difficult problems which daily confront them, the hostile cry of ignorant criticism, which is so often directed against them, would be forever silenced by their discoveries for the commonweal.

HIGH IDEALS IN THE STUDY OF LARYNGOLOGY.

The study of laryngology will never reach the full fruition of its hopes and aspirations until it becomes the inspiration of a higher effort and a loftier ideal.

Let it teach the student not to contract, but to broaden the horizon of his intellectual activities. Let it make him understand that the laryngoscope is not merely a device for exposing hidden recesses of the body and for the demonstration of that which is already known; but an agent of positive power in future research—a means of scientific expansion and exploration of the unknown. Let laryngology walk with becoming humility beside the great pioneer forces of human endeavor, aiding them, it may be, in an humble and unostentatious way, but still contributing to their progress through the trackless wilds of the land that is untrodden and unknown. Undaunted, undismayed, let them together press forward until the wilderness shall blossom as the rose and Nature's wild forest ring with the shout of their exultant discovery. When this ideal shall have been attained and this conception of our art is realized, then will the study of laryngology blaze the way for the triumphant march of scientific medical achievement, and the laryngoscope will become an instrument of progress and power.

SIMPLE GINGIVITIS, ITS ETIOLOGY AND TREATMENT.*

GEO. T. CARPENTER, M.D.

CHICAGO, ILL.

Disease of the human gums, in these days of advanced civilization, is very common and almost universal. In fact, it is a rare thing to find gums that are in all their margins perfectly free from irritation, inflammation, hypertrophy, atrophy, or absorption, and many will show evidence of gingival ulceration. At three previous meetings of this Section I have presented papers closely connected with the present subject. The conditions then studied were the result of advanced inflammatory or suppurative processes; but by the term "simple gingivitis" I include only that condition of the gum margin about the necks of the teeth, known as the gingiva, that shows the slightest departure from health, but is fully established and persistent in its nature. It is the purpose of this paper to take gingival irritation in its simplest form and point out its etiology and treatment, and in this way prevent the subsequent and more serious diseases, which by their certain progress result in pain, discomfort, loss of tissue, and eventually the loss of the teeth themselves. Gingival irritation is liable to present itself at any point where there is a gingival margin. We may find the gingiva of one tooth inflamed and the rest of the gums in a healthy condition. We may find the anterior teeth in a clean condition but affected by gingivitis, while in the posterior teeth, which receive less care, the gums may be in good, healthy condition. We may find gingivitis in some, or all, the gums in well-kept mouths, and we may find exactly the same condition of gums in mouths that do not receive the slightest care or attention. We will find this form of inflammation in the mouths of the young, those in middle life and old age. We will also find it in the anemic and emaciated, also in the well-nourished and rugged. This condition, which is found in the human mouth, is rarely found in the mouths of lower animals in their natural state, and from some experiments on the gingiva of rabbits I find that it is almost impossible to establish a gingival irritation without using some powerful infections or poisonous substance. We also find that in the human mouth where bands, clamps, wedges, or ligatures have caused some irritation and even laceration, that a gingivitis does not as a rule result, so that the etiology of this apparent slight trouble is varied and very obscure. The etiology or local causes: Irregularities and malocclusion are factors; also imperfect or loss of contour; improper use of the teeth or, more correctly, insufficient use of the teeth, causing lack of tone to the gum; inortitled. It, therefore, marks an important era in the evolution of the undergraduate study of laryngology. If for no other reason, then, as a matter of historical interest, I will ask attention to the method of teaching the specialty which has been adopted in this institution. I shall content myself with simply giving a mere outline of the work, and shall not enter into matters of detail.

STUDY OF LARYNGOLOGY IN THE JOHNS HOPKINS *MEDICAL SCHOOL.*

The time required for the degree of Doctor of Medicine is four years, of nine months each. The requirements for entrance to the medical school are rigid, only those being admitted who give evidence of having had a liberal education as indicated by a collegiate degree in arts or science, including an acquaintance with Latin, a reading knowledge of French and German, and adequate training in physics, chemistry and biology. The first two years are devoted mainly to practical work of all kinds in the laboratories of anatomy, physiology, physiologic chemistry, pharmacology and toxicology, pathology and bacteriology. During the last two years much of the students' time is spent in practical work in the wards, laboratories and dispensary. It is not until the fourth year that the class enters the special departments. It is my intention to give a course on laryngology in the third year, so that when the student enters his graduating or fourth year course, he may be at least familiar with the use of the mirror. I mention these facts simply to show that, when the student reaches me, he is quite thoroughly trained, not only in the use of his brain, but also in the use of his hands. By constant practical work for three years, he has acquired an amount of manual dexterity which enables him to master the art of laryngoscopy with relative ease.

The graduating class is divided into four sections—each section (of the fourth-year class) attends for one and one-half hours daily during two months, the laryngological and rhinological department, where they receive practical instruction from my assistants and myself. After preliminary drilling in the use of the laryngoscope and other technical procedures, and in diagnosis, the student assumes the work of clinical assistant. He is given pathologic material for examination and diagnosis, and is encouraged to report cases and read papers before the Hospital Medical Society, to look up the literature of interesting subjects connected with laryngology, to observe for himself and, if he has time, to do original work. He is taught to investigate and to enquire, and I may say just here that it often requires a very high order of human ingenuity to construct an evasive answer to some of the conundrums with which I am frequently assailed. He takes his first lesson on the human subject —gets his first impression from Nature. I formerly used models; but some one stole them and I am glad they are gone.

By the above method, the teacher comes into direct personal contact with each member of the class, and is enabled to measure the mental status of the individual. In no other way can laryngology be properly taught. It is hard work, but it pays in the results which are accomplished. Laryngology can not be taught by text-book or lecture. It must be taught over the shoulder of the instructor, and on the part of the student, must be acquired by direct contact with, and personal observation on, the living subject.

While the didactic lecture is fast becoming an anachronism, I do not believe that the day of its usefulness is completely gone. I give a systematic course of weekly lectures to the entire class, which are supplemented by pathologic and clinical demonstrations, on the anatomy, physiology and commoner diseases of the upper air-passages and their relations to morbid processes in other parts of the body. In this course especial attention is paid to diagnosis. The object of these lectures is two-fold: 1, to give in a concentrated form and in the shortest possible time information which could not be acquired except by great additional labor on the part of the student, and 2, to avoid endless repetition in the section room.

In the matter of text-books and literature, the class is shown the principal works and current periodicals in English, French and German. No special text-book is recommended or required; but, in connection with the lectures, the students are referred to special articles and monographs containing the classic literature of each special subject.

The question of the value of examinations is a very important one and one which is destined soon to be pressed to final settlement. While I can not go as far as my gifted friend and colleague, Professor Mall,[1] who is of the opinion that it would be well to separate them from the course of instruction entirely, I must confess that I am very much in sympathy with him in the main points of his contention. But until a more rational and exact method of accomplishing the same results be devised, I am afraid the examination must remain as a necessary evil. It is often a farce. One of the best examination papers I ever received was from a student who, on account of a serious illness, was compelled to absent himself from the very lectures on which the class was being examined. He had used the notes of a fellow-student and came back at me almost with my own words. In the university in which I received my first medical degree, instruction, except in the department of anatomy, which was practically and ably taught, was entirely by didactic lectures. We sat all day in the lecture-room taking notes, and spent the entire evening "cramming" them for the next recitation. We never saw a medical case. Once during the session, the professor of surgery brought in the colored janitor, stripped him and bandaged his legs and arms. This was our only course in practical surgery. Those were the good old days when, as Mall says, the students "heard much, saw little and did nothing." When the day of examination arrived I knew my text and note books from cover to cover, and could locate with unerring accuracy any required item of information to the page and to the line. My memory was so saturated with medical lore that it took me some years after I left college to forget it. I was invincible in the examination room, but helpless at the bedside.

The best examination is the observation of the student in his daily work and the resulting estimate of his personal equation. During the first two years I gave an oral examination at the end of the term, carrying each student over the entire field covered by the lectures, but, as the size of the class increased, this had to be abandoned, and I now give a single written examination, of which the following, which was my first, is an example.

1. Give the physiology of the nasal and accessory cavities.
2. General symptoms and diagnostic signs of suppuration in the nasal accessory cavities—diagnosis of pus in the antrum maxillare.
3. Early laryngoscopic diagnosis of tuberculosis and cancer: characteristics of syphilitic, cancerous and tubercular ulceration in the upper air-passages.

SIMPLE GINGIVITIS, ITS ETIOLOGY AND TREATMENT.*

GEO. T. CARPENTER, M.D.
CHICAGO, ILL.

Disease of the human gums, in these days of advanced civilization, is very common and almost universal. In fact, it is a rare thing to find gums that are in all their margins perfectly free from irritation, inflammation, hypertrophy, atrophy, or absorption, and many will show evidence of gingival ulceration. At three previous meetings of this Section I have presented papers closely connected with the present subject. The conditions then studied were the result of advanced inflammatory or suppurative processes; but by the term "simple gingivitis" I *include only* that condition of the gum margin about the necks of the teeth, known as the gingiva, that shows the *slightest* departure from health, but is fully established and persistent in its nature. It is the purpose of this paper to take gingival irritation in its simplest form and point out its etiology and treatment, and in this way prevent the subsequent and more serious diseases, which by their certain progress result in pain, discomfort, loss of tissue, and eventually the loss of the teeth themselves. Gingival irritation is liable to present itself at any point where there is a gingival margin. We may find the gingiva of one tooth inflamed and the rest of the gums in a healthy condition. We may find the anterior teeth in a clean condition but affected by gingivitis, while in the posterior teeth, which receive less care, the gums may be in good, healthy condition. We may find gingivitis in some, or all, the gums in well-kept mouths, and we may find exactly the same condition of gums in mouths that do not receive the slightest care or attention. We will find this form of inflammation in the mouths of the young, those in middle life and old age. We will also find it in the anemic and emaciated, also in the well-nourished and rugged. This condition, which is found in the human mouth, is rarely found in the mouths of lower animals in their natural state, and from some experiments on the gingiva of rabbits I find that it is almost impossible to establish a gingival irritation without using some powerful infections or poisonous substance. We also find that in the human mouth where bands, clamps, wedges, or ligatures have caused some irritation and even laceration, that a gingivitis does not as a rule result, so that the etiology of this apparent slight trouble is varied and very obscure. The etiology or local causes: Irregularities and malocclusion are factors; also imperfect or loss of contour; improper use of the teeth or, more correctly, insufficient use of the teeth, causing lack of tone to the gum; inorganic substances used as dentifrice, causing unnatural or insoluble deposits under gum margins, which is most common in the lower jaw; the injudicious use of toothpicks; floss and rubber bands, keeping constant irritation at given points.

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

Constitutional Causes: A defect in nutrition or cachectic condition may cause an isolated gingivitis at a given point, just as the same condition may produce an aphthous ulcer at any point on the mucous membrane of the mouth. The same cause which results in dyspepsia, constipation, sick headache, dyspnea, and a host of other symptoms, also cause gingivitis.

Improper Nourishment: This is often the result of too much preparation of food for the teeth and stomach. Plain, coarse, wholesome food that will give the teeth something to do will act as a proper stimulus to the gums and will be kindly received by the stomach. The colored people at the close of the Civil War had mouths with healthy gums and teeth free from caries, but higher civilization, mingled with hotel and restaurant cooking, has so changed conditions that their mouths now are filled with both caries and disease. Careful examination of the mouths of many of the peasants emigrating from Europe, have led me to believe that the care of the mouth should be principally through the stomach and a thorough use of the teeth by mastication of food.

Treatment: Correct all mal-occlusions and restore perfect contour to crowns. Remove all local irritants and deposits and make a light application of tincture of iodin to affected parts and give instructions to prevent irritation and abuse of gums; change diet from mashed vegetables of all descriptions or soaked or cooked in milk to that of dry or Swedish toast, whole wheat, or grape-nuts; to be ground thoroughly fine with the teeth, incorporated with the saliva and swallowed. This treatment should be followed, especially with children suffering from gingivitis.

I am indebted to Dr. M. H. Fletcher, of Cincinnati, for the suggestion of corn-meal as a dentifrice. I think as a partial substitute for thorough mastication that a good cereal dentifrice is very beneficial, using corn, oats, cream of wheat, or any coarse and grainy substance, and brush the teeth and gums vigorously after each meal and before retiring, giving a half rotation to the brush. The mouth should be thoroughly rinsed after each brushing, as there is some difficulty in removing the cereal. I do not approve of the use of a very stiff brush without a dentifrice, and I consider the place for all inorganic dentifrices is on the outside of the mouth. They may serve a good purpose for cleansing metals and marble, but should not be used on organized tissues.

103 State Street.

DISCUSSION.

Dr. G. V. I. Brown, Milwaukee, Wis.—The essayist states, after describing the simple forms of gingivitis, that gingivitis more often proceeds from the apices of the roots toward the gingival margin than from the gingival margin to apices of the roots. That was the point Dr. Talbot made clear some time ago. He said in our treatment of pyorrhea alveolaris we pay too much attention to palliative treatment. He said he considered our diseased gums from the gingival margin, whereas a mild inflammatory process was going on very much in advance of what we could see with the naked eye. Upon that simple fact I have based what treatment I have attempted ever since, and I think when we realize that, we have got all we need for that which comes directly within our own province. We must admit that every general condition which interferes with the excretory organs in any way will certainly render the tissues of the body more susceptible to the inflammatory process than they would be otherwise. If an interference with these organs in the performance of their natural functions will render the cure of any inflammation more difficult, and contraindications would complicate this state of affairs, so far as we are concerned we have all we can do to take care of the local matter. If we recognize the fact that these inflammatory changes are going on beyond the point we can reach in our treatment, beyond the point our profession is capable of exploring, then we must in some way relieve the local condition, and it is impossible to have a case of pyorrhea where you have that contraindication without having the occlusion of the jaws interfered with, and you can not cure that condition locally as long as the occlusion of the jaw is imperfect, and by this irritation of the surface you continually increase that inflammatory condition in spite of all you can do. I will probably bring down a storm of scientific criticism upon my head, but if I can not do more than to bring out the valuable point Dr. Talbot brought out years ago, I shall be satisfied.

Dr. Eugene S. Talbot, Chicago—I am very much pleased with the conclusions of the essayist and the remarks by Dr. Brown. I am glad Dr. Brown has given this subject so much attention since I first outlined the pathology of this trouble. Both essayist and Dr. Brown are correct. Dr. Carpenter has taken up the local condition and causes of the diseases, and Dr. Brown has taken up the constitutional side of the question. There are certainly two factors in producing simple gingivitis, the local and the constitutional. I must, however, go back further than either of these gentlemen in order to get to the real condition and cause and that is the point where individuality must obtain treatment. Transitory structures are involved and the fact must not be lost sight of that the jaws and teeth are passing from a large and strong jaw to an extremely weak one; these changes are going on very rapidly, indeed, with our present mode of living. Dr. Carpenter said in his paper that the lower animals are not involved in this change in their "natural or undomesticated" state. These structural changes go on in domesticated lower animals as they do in man. Dogs have undergone a change, as Dr. Kiernan said yesterday, in certain structures the same as man. Gingivitis occurs in horse and cow in the fall of the year when the animals are taken from the pasture to the stable. The horse after being put in the stable will catch hold of the manger and pull with his teeth making a piping sound. This indicates there is irritation in the gums with resultant inflammatory action. The same is noticeable in the cow in trying to grind her teeth. In transitory or unstable structures inflammation sets in quicker than in any other structures. This is true alike of the appendix and the jaws and teeth. Wherever these changes occur in the systemic condition from disorders like indigestion or diseases such as typhoid fever, it is manifested here. Especially is this true of little children. I have noticed particularly in degenerates, such as in the deaf, dumb, blind and idiots, that there is marked inflammation of the gums. So the abnormal condition of the structures must not be unheeded in the treatment. A writer in the June *International Dental Journal* of Boston claims that the gum should not be massaged. He has a brush composed of badger's bristles, a very soft brush. He claims that if at all only a very mild massage should be done and the fingers should be used. The opposite from actual experiments seems to me alone justifiable. The essayist states that a very strong brush should not be used; I should use the stiffest brushes upon the gums. It is not the gum that is being injured as the alveolar process is absorbing away; it is the interstitial tissue. The gums become involved, but there is no danger of absorption. The blood is forced out of the gums and they contract to secure a healthy alveolar process. Absorption of the gum is not the danger, but absorption of the alveolar process. The gums contract down to it. The gum should be massaged with a stiff brush and tincture of iodin should be used to reduce this inflammation. Inflammation takes place in nearly every patient. The blood shows that pathologic conditions have set in. To reduce the gums to their healthy condition, use a stiff brush and massage them three or four times a day.

Dr. Vida A. Latham, Rogers Park, Ill.—When we speak of simple gingivitis, the majority of people consider at once pyorrhea alveolaris! Let us take a case for example: A woman comes to your office, an apparently healthy case, perhaps the mother of a family. Her general history is good but she may be a little anemic. She has a magnificent set of teeth, but we meet with a little discoloration of the gums. What is it? It is nothing more nor less than the outcome of simple gingivitis. I do not care to hear anything about the pyorrheal condition, or whether it is a passive or active congestion, or if by pressing with the finger you can get blood or pus, provided it has reached the suppurative stage of the inflammatory condition. That is not the point. We mean simple gum infiltration. Therefore, I would like to have somebody go back to the beginning and give us the early stages of what may become sooner or later interstitial gingivitis. For example, here is a case of lung disease. Is it pneumonitis? You may have it in the upper lobe or the second lobe or all the lobes, but it may enter upon resolution, clearing up everything and the parts return to the normal. If you get a pneumonitis and it does not all resolve you may then get an increase of fibrous tissue, which would be called a cirrhosis or interstitial or fibroid pneumonia; you may have an increase in size or a decrease and the result is the same; it is a thickened sclerotic condition. It is this distinction which I think our dental pathologists have confounded with the later stage. When we are called upon to treat this early simple irritated state we fail to recognize or treat it previous to its entry into one of the most serious and advanced terminations of inflammation. It may certainly become fibroid, abscessed, ulcerated or even gangrenous. I prefer to ask you to deal with the simple congestive or irritated condition which is the early simple gingivitis even if recession be present, or swollen edematous puffy tissue of the gums so well known in unclean mouths. Here is a child that is degenerate, but the simple and interstitial inflammation is not necessarily a degeneration. I think our dental pathologists are very lax in this matter. We have different forms of gingivitis, some are chronic, some are acute. The gum has receded, there is a great deal of hyperesthesia, a continual irritation, everything the patient touches makes the teeth ache. I would like to have a remedy for this early condition. I have several cases on hand which I do not know how to treat. I have tried massage, local and general treatment; I have cleansed the teeth. I have used anesthesia to find salivary calculi on the roots and I can not find much wrong. These are cases I wish a special classification for. Why should we not have early simple as well as the chronic or interstitial gingivitis with recovery. This is a condition I would like to bring to your notice and ask for a remedy as well as for more research into this, the very beginning of the disease, and so prevent the loathsome and dreaded "pyorrheal states" and its recession or absorption of the alveolus as illustrated so ably by Dr. E. S. Talbot in his work on so-called "Pyorrhea Alveolaris."

DR. G. V. I. BROWN, Milwaukee, Wis.—The trouble is we have taken too narrow a view of this matter. In pyorrhea or gingivitis, when you come to cut off the state of inflammation and classify under one name or another a condition which to-day may be one thing and to-morrow another, you are making a classification which will not stand, but this distinctive condition which we recognize as pyorrhea is simply one form of the condition which we have brought to our notice as dentists. An inflammation may be destructive or constructive. We have just as frequently in some cases a condition which causes a change in the pericementum. This is evident to us, particularly when a tooth is attempted to be extracted. The process comes away with it; there has been a change in the membrane, that which has formed this union of the surrounding bone to the pericementum in a way that has become almost inseparable. Under these conditions we find many patients. A large number of the chronic neuralgias come from this condition of the membrane. In addition to this, we have certain structural changes in the dental pulp itself. These changes all occur as the result of some nervous disturbance due to the excitement of the centers which control the muscles of mastication. They continue working and grinding, which causes a local and general disturbance which is greater than we have any idea of. I think I have a half bushel of casts showing the stress due to habit, and in these cases sometimes a paroxysmal pain occurs every few minutes and continues for years until the patient is a physical wreck. I have a number of cases now that have had to be cared for as a result purely and simply of this habit. Again we have a pyorrhea which we recognize easily, and we have pulpitis due to the loss of the surrounding tissue. But these conditions due to the same causes aggravate all these other conditions, because when the excretory organs are out of order the nervous conditions are worse. Taken in its broad sense there is no longer any question as to the marked etiologic factor in pyorrhea. The way to all this has been made clear by Dr. Talbot.

DR. A. E. BALDWIN, Chicago—Before this subject is passed, I want to claim that I believe that these gentlemen have been discussing something else than the paper. The paper is on the subject of simple gingivitis, simple inflammation of the gingiva or gum. You must not say in an assembly of sane people that you can have a simple inflammation and have it absorbed by the body. I do not think any sane man would make such a statement. I may say to you that I learned years ago in the medical college that there could be simple inflammations, and the meaning of the word "simple" is "without complications." We may have simple inflammation of the lungs; we may have simple inflammation of the pleura; we may have simple inflammation of the gums, and when anybody gets up before this Section and says the best way to quiet an inflammation is to jump on it, to tread on it, to strangle it, to scarify it, it seems to me wrong. I think oftentimes with some of these local irritations we are not discussing interstitial, but we are discussing simple gingivitis. The amount I do not know about a great many of these subjects would fill a book, but there are some things I feel I do know, and I know that simple gingivitis is simply an inflammatory process of the gum itself, not complicated with suppuration, not complicated with anything, but just what the name means. About as good a plan as you can follow is to give the part rest, quietude, something soothing. I believe that is our first duty. There may be complications that may be treated and treated wisely, but it seems to me this talk has been largely upon a question that is far from the paper as read.

DR. GEORGE T. CARPENTER, Chicago—I would like to say a word in closing in regard to the word "simple." It was my intention by the use of this word to include only the gingivitis in its simplest form and to avoid "interstitial gingivitis," or pyorrhea alveolaris. It was distinctly understood that the term "interstitial gingivitis" should not be used so as not to have the subject misconstrued. I stated certain conditions as not coming under the head of this paper, but emphasis was placed on the simplest conditions. This does not even result in ulceration in many cases, but it is simply an evidence of that slight affection of the gingival margin that does not get well. These conditions lead on to something more serious, and what we are trying to do is to get at the cause and treatment of this condition. Dr. Brown speaks of the local causes, but I spoke of the constitutional causes. A constitutional cause is directly responsible for this condition. As I said in my paper, it is almost an impossibility to establish this condition unless there is a departure from health. There may be no sign of anemia, but where there is a departure from health or a disturbance of the circulation we establish gingivitis.

In speaking of the animals in their natural state, I did not take into consideration dogs, horses and cows for the reason that they are domestic animals and are fed by man. I mean the wild animals, and I have never found a case of gingivitis in wild animals. There may be cases, but not as a rule. It is under this artificial condition only that we find gingivitis.

In reference to the tooth brush, its use is simply applying Nature's cleansing materials to the mouth. We are not chewing inorganic substances. Our teeth are only intended to masticate vegetable and animal substances. and through contact of these substances to the teeth and gums is Nature's process. That is the reason I object to the use of the stiff tooth brush. I think it is an unnatural process, and I depend upon the cereal more than the stiffness of the brush. The object in this is to give tone to the gum. What we want is to stimulate the blood supply, and we do this with a cereal carried on a tooth brush, which partially takes the place of the failure to properly masticate proper foods.

We see defects in the teeth that we know are only slight, but that will in our judgment become more serious; and we urge the necessity of these defects receiving prompt attention. We do not place the same importance to defective conditions or disease of the gums. That is why there are more teeth lost in this condition than from caries. As long as a tooth is perfectly sound there is no need of the dentist, but as soon as we see any changed or defective condition we should always be serious with our patient and explain the danger. When the gums are diseased there is something the matter with them, just as much as if there were a dozen cavities in the mouth, and no dentist would allow decay to go on. They would call it imperfection of the teeth. This is simple gingivitis, and it is growing worse instead of better and will ultimately result in the loss of those organs. We want to sound a warning and educate our patients up to this fact and give them to understand that we mean exactly what we say, and the loss of a few teeth with an explanation will probably result in an education that will do much good.

Dr. R. R. Andrews, Cambridge, Mass.—I have had considerable discussion with Dr. Sargent on the want of use of the teeth by children. It is a fact that children eat too much of soft mush; they do not use the teeth enough, and although it is a very disagreeable habit, I think there would be an improvement of the teeth if the children were encouraged to chew gum. There is no question but what the chewing of gum is a good stimulative process and puts the teeth in a good, healthy condition. Our children do not live right. They are fed on these soft materials and their teeth do not have the use they were meant to have.

There is another thought that occurred to me. Dr. Williams has, without any doubt, demonstrated that there is in the mouth, more particularly on those teeth where the mouth is full of decay, a microscopic form of germ. He has demonstrated that this micro organism, the leptothrix bacillus, is constantly going to the extremity of the roots, myriads upon myriads. Let any one have a patient take a little iodin and put it around the teeth. I have had patients come to me and ask how they should keep their teeth clean. I told them to brush them morning and night and put a little iodin on and they will be surprised at the result. I think great good comes from the treatment as practiced by Dr. D. D. Smith, of Philadelphia. He takes a piece of orangewood of a V-shape and goes around the teeth inside and outside the occlusal surface. Dr. Smith makes the astounding statement that bad breaths are cured, that a pyorrhea alveolaris is cured. Dr. Smith has under his care a patient who has been treated for two years for pyorrhea, and he has recently been using this treatment, stimulating the gums with this stick, going under the gums as well as cleansing them thoroughly, and he made the statement before the Boston Dental Society that he had never had so much success as he has had with this method after using it only three months. There is certainly something in that. These germs are hidden under the gum, but this stick goes all around and under the gum, thoroughly cleansing it, and in that way he gets rid of a great deal of this injurious matter.

Orthoform Test for Gastric Ulcer.—Mennini states in the *Riforma Medica* of May 18, that it is possible not only to differentiate a gastric ulcer with orthoform, but also to determine its location. After ingestion of one gram of orthoform dissolved in half a glass of water, the pain from an ulcer vanishes in twenty minutes, and does not reappear for three or four hours. The analgetic effect is not experienced in certain cases unless the patient lies in the ventral or dorsal decubitus, according as the ulcer is located in the front or rear wall of the stomach. The orthoform has no effect in cases of simple gastralgia with the mucosa intact. The pain continues uninfluenced by it.

MILITARY DENTAL PRACTICE—ITS MODIFICATIONS AND LIMITATIONS.*

HENRY D. HATCH, D.D.S.
NEW YORK CITY.

What shall the new military practice consist of? What are its limitations and modifications, and how must the conservative civil practice be modified so as to best serve the interests of the army and the individual soldier? These are the questions with which it is the province of this paper to deal.

There are certain branches of dentistry which to-day, as it exists, it would seem wise to eliminate altogether, namely, prosthetic dentistry, orthodontia, crown and bridge work, and gold filling.

Prosthetic dentistry would be impracticable for the following reasons: 1. The appliances necessary for the construction of artificial dentures are cumbersome and would add that much more to an already overburdened transport service. 2. The time required to do such work is more than could be spared, owing to the few surgeons assigned to the service.

That orthodontia would have no place in military surgery is self-evident to any dental surgeon.

Crown and bridge work would hardly be feasible, except, perhaps, at certain army posts, for the reason that to be of any value it must be done with a certain nicety requiring much time, many additional instruments and much expensive material.

Gold filling is placed in this category for much the same reason. Gold filling, to be of any value, must be done under the most propitious circumstances, requiring a good chair, good assistants, dry, clean surroundings, many fine instruments and plenty of time; the item of time is the most important in this case, as, with the present limited number of surgeons, to give the necessary time to one man would probably rob others of needed attention.

Eliminating, then, all the above, there still remains work enough for the most energetic and able men.

THE OUTFIT.

Let us now briefly glance at the positive side of the question. Other things being equal, the dental service will be popular in the army, as it takes up little room, demands few transportation facilities, and adapts itself to the prevailing conditions easily and uncomplainingly. The outfit, then, should be as small as is consistent with good work; everything should be snugly packed and capable of being unpacked and packed again in the shortest possible time. One of the lessons taught by the Boers in their struggle for independence is that the modern army must return to the practice of Julius Cesar, where luggage was reduced to the minimum. A portable headrest attached to an ordinary chair would have to take the place of the ordinary dental chair, except at regular army posts. Anesthetics could be given on the operating table of the general surgeon, or on a cot bed. The instrument case could be mounted on a tripod or a table, and made to take the place of the usual cabinet.

An instrument sterilizer should, by all means, be made a part of the outfit, such as a Schering formaldehyde sterilizer, or the smaller one as modified by Dr. Stanton of New York, or the formaldehyde sterilizer devised by Dr. Low of Buffalo, which is perhaps more cheaply and easily operated.

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

Formaldehyde gas must prove to be the ideal sterilizing agent in military as well as civil dental practice. It requires a very small quantity of spirits to generate the gas. As previously pointed out to the profession by the writer, boiling is the cheapest and most ready method of sterilizing where the nature of the instruments and appliances admits of boiling; but with dental instruments we have the mirrors, which can not be boiled; also corundum wheels, engine hand-pieces and many other things. But whatever the method, it is to be hoped that the dental surgeons will not lag behind the general surgeons in this respect.

OPERATIVE DENTISTRY.

The dental surgeon will at first be most often called upon to relieve pain, either by extracting or treating exposed pulps, alveolar abscesses, etc., and here is where the high character of the men selected by our excellent examining board will have a chance to show itself, and prove to the army and the nation that the modern dental surgeon is something more than a mere tooth-puller.

Extracting may have to be done more often than in civil practice; but by using good judgment and adopting means adapted to the exigencies of the service, extracting may be reduced to the minimum.

Certain pulpless molar teeth, which in private practice would be sterilized and filled to the ends of the roots, might be saved by using some of the mummifying methods—preferably Miller's—always with some filling over it that could easily be taken out, if need be, and the pulp chamber and canals redressed. In certain cases, extracting might be avoided by opening into the pulp chamber at the cervix and waiting until the case could have more thorough treatment. At any rate, root-filling should not be attempted unless the operator has the time and the facilities to do it thoroughly.

In the minds of the laymen, or the common soldier, "nothing succeeds like success," and in the first years of this experiment (for such it is evidently considered by the government) it will be well to undertake nothing which does not promise to succeed.

In extracting and other surgical work it is to be hoped that anesthetics, either local or general, will be used as they would be in civil practice. Even a soldier ought not be called upon to endure more pain than is necessary. Besides, many will be either in the hospital or on the verge of it, when rough treatment and shock might be the last straw. Any tendency to become brutal or rough on the part of the dental surgeon should meet with prompt rebuke or dismissal from the service.

The dental surgeon will have plenty of opportunity to observe and treat diseased conditions of the soft and osseous tissues surrounding the teeth. If they are carefully observed and accurate records kept, much will be added to our meager knowledge of these conditions. The dental surgeon will see conditions caused by both mercury and the need of mercury, and perhaps will be able to get truer histories in the army than out of it.

That dental surgery merges into oral and general surgery, so that a dividing line can hardly be drawn, goes without saying. Hence, it is to be expected that the dental surgeon will have much to do with fractures and gunshot wounds involving the maxillæ. The use of interdental splints made of vulcanite or swaged metal would hardly be applicable in military practice for the reason given above concerning prosthetic work. In their place there could be substituted something after the Angle system of easily adapted bands and ligatures, or an easily made splint consisting of metal bands connected by hard solder to heavy platinum and gold, or iridio-platinum, wire—the piece made loosely fitting on a cast gotten from a modeling composition impression, and cemented in place. An interdental splint, in many instances taking the place of vulcanite, may be made quickly and easily by cooling and trimming two side "bites" of modeling composition. In cases of resection of a considerable portion of the inferior maxilla, such a side "bite" of modeling composition, put in place immediately, answers an excellent purpose.

IDENTIFICATION BY THE TEETH.

For the purposes of identification, after disaster by fire or flood, or other causes, where clothing is destroyed or the soft parts decomposed, experience has proved that identification by the teeth is the only reliable one. The condition of the bodies after the disaster to the battleship *Maine*, and after the catastrophe of Bazar de la Charité in Paris, May 4, 1897, and in many other instances, prove this. Therefore, it is urged that the Government be memorialized to the effect that all officers and men in the army and navy, and all who shall be mustered into the service, shall have charts and casts made of their teeth by the dental surgeons of the army, or others appointed for the purpose, such charts and casts to be properly inscribed and filed with the proper departments for reference in case of death or desertion.

It would seem that with the training the dental surgeon has received in aseptic methods and in minor surgery, he might be an excellent assistant to the general surgeon in emergencies, after battles, etc., thereby tending to promote mutual regard, and a better understanding between the two professions, now separate, but destined to become one.

OPENING DISCUSSION ON "MILITARY DENTAL PRACTICE—ITS MODIFICATIONS AND LIMITATIONS."*

JOHN S. MARSHALL, M.D.
PRESIDENT EXAMINING BOARD DENTAL SURGEONS, U. S. ARMY.
ST. PAUL, MINN.

The passage of the Army Reorganization Bill with its section creating a Corps of Dental Surgeons for the U. S. Army, makes an epoch in the history of modern dental surgery; an epoch which has never had its counterpart before in the history of the world, the influence of which is destined to be far-reaching in its beneficent results, and of great importance in the elevation of our educational and professional standards.

When we take into consideration the fact that modern dentistry covers, in its growth and development, a period less than the lifetime of many individuals, we have good reason to be proud of its achievements. Sixty years ago there was no such thing in existence as a dental college; a dental journal had not been thought of, or a scientific dental society organized. The practice of dentistry at this time was, with few exceptions, in the hands of the barbers and blacksmiths. The few earnest scholarly men who had entered its ranks were desirous of lifting their specialty out of its low estate, and by education and scientific training make of it an honorable and worthy calling. In this endeavor, however, they met with no encouragement at the hands of their confrères in the medical profession, but, nevertheless, with these great odds against them, engendered, not by malice, but by the narrow view taken by those unfamiliar with the capabilities and possibilities of develment which lay in this infant specialty, they moved rward and laid the foundations of what has proved be one of the greatest specialties in the whole field f medicine.

---

* See preceding article.

We have special reason for congratulation also in the act that the Congress of these United States was the rst legislative body in the world to formally recognize he *value* and *need* of the beneficent services of our specialty as a department of military medical practice, nd that we have been given an opportunity to prove he wisdom of its action to our country and the world.

The whole question, however, of placing dental surgeons in the Army was looked upon by many of our national legislators in somewhat of the light of an experiment, and in a certain measure this is true of the War Department and of the Surgeon-General. For this reason, when the bill was framed it was thought best to provide for the organization of the dental corps upon the contract system, as by this system it would be an easy matter to discontinue it if it should prove unsuccessful; while upon the other hand, if its service was a success, and found to be an indispensable part of Army medical practice, the Corps could be made permanent by amending the law so as to make its members commissioned officers.

The examinations of the Dental Corps and the selection of the outfits have been placed in the hands of an Examining and Supervising Board of Dental Surgeons, subject to the approval of the Surgeon-General and the Secretary of War. These officers have invariably sustained the Board in all of its work; have given them every facility asked for, and rendered every assistance possible in planning the organization of the Corps and insuring its future success in the field.

European nations will be interested in the plan of organization of our Army Dental Corps, of its personnel, and the results of its professional services. Upon the success or failure of this enterprise will depend in a large measure the introduction of a similar service into the armies of other nations. It is to be hoped, therefore, in the interests of humanity that it may prove successful.

I have been interested in reading the paper of the essayist, and feel like complimenting him upon his apparent grasp of the subject under discussion. His suggestions as to the modifications and limitations of military dental practice are in many respects good, but it will not be necessary to confine Army practice within such narrow limitations as he has outlined.

The general suggestions which he has made and many more of a specific nature have formed the subjects of much earnest consideration upon the part of Surgeon-General Sternberg and the Examining and Supervising Board, and not until each question has been carefully weighed and the consequences of its adoption or rejection examined from all standpoints, has final action been taken. The progress of organization has been necessarily slow, for there were no established precedents to guide the Board in its actions, and no past experience to enlighten it. It has, therefore, been obliged to begin its work at the very foundation, striving to lay this *firm* and *sure*, and then gradually to rear upon this the superstructure of a finished organization. The organization of the Dental Corps is yet in the experimental stage; the authorities must therefore carefully feel their way and adapt the service to the peculiar demands of military life and movements, making such changes from time to time as experience and foresight shall dictate.

With the approval of the Surgeon-General, I herewith present in brief outline the plan upon which the Army Dental Corps is organized. This outline comprises:

1. The official status and pay of the Army Dental Surgeon.
2. Examination of candidates.
3. Assignment to duty.
4. Regulations governing the Dental Corps.
5. The supply table.
6. Nosological table and system of keeping records.

THE OFFICIAL STATUS.

The Army Dental Surgeon belongs to the regular establishment, and according to the law which created the Corps, he will serve the officers and enlisted men of the regular and volunteer armies. He is employed as a Contract Dental Surgeon, having the *relative* rank of a first lieutenant. His pay is $150 per month, and quarters when serving with troops. All instruments, apparatus and materials are furnished by the Medical Department that are necessary for conducting his practice and performing his official duties.

THE EXAMINATION OF CANDIDATES.

The examinations consist of *a*, physical condition; *b*, written and oral questions upon the studies of the dental college course; *c*, practical demonstrations in operative dentistry; *d*, practical demonstrations in prosthetic dentistry.

a. The physical examination is conducted by an army surgeon detailed for this purpose, and upon the same general lines as those in vogue for entrance into the other departments of the Army. Perfect health and freedom from physical defect are necessary to pass this examination; but defective eyesight which can be corrected by appropriate glasses does not debar the candidate.

b. Written and oral examinations are conducted upon the following-named subjects, and the candidate must attain a general average of 75 per cent. upon each of them:-Anatomy, physiology, histology, chemistry, physics, metallurgy, dental anatomy and physiology, dental materia medica and therapeutics, dental pathology and bacteriology, orthodontia, oral surgery, operative dentistry, prosthetic dentistry.

c. The practical examination in operative dentistry consists of the following: 1. Examination and recording the condition of the mouth and teeth. 2. Preparation of cavities, 1, by hand instruments; 2, by engine instruments. 3. Instrumentation and technique. 4. Preparation and manipulation of filling materials: gold, tin, amalgam, gutta-percha, oxyphosphate, cement. 5. Insertion and finishing of fillings. 6. Treatment and filling of root canals and preparation of root for pivot crown. 7. Manipulative technique in removal of calcarious deposits. 8. Application of rubber dam, metallic separators, matrices, etc. 9. Diagnosis, prognosis, and treatment of oral diseases. 10. Care of and sterilization of instruments and hands.

d. The practical examination in prosthetic dentistry comprises: 1. Impressions, casts, bite and articulation (occlusion). 2. Construction of denture in vulcanite. 3. Construction of dies and counter-dies from impression to completion. 4. Construction of swaged plate, with metal and rubber attachment. 5. Construction of inter-dental splints. 6. Construction of Richmond crown.

Upon all clinical or practical demonstrations the candidate must attain a general average of 85 per cent.

The reason for this higher requirement in the practical branches is made evident by the statement that practical men are needed in the service, not theorists. But it may also be stated that practical ability alone would be of little value in military dental practice. The dentist to be successful in this new field of practice must be thoroughly informed upon all those subjects and theories which form the foundation of modern dental surgery. He will need to be self-reliant and capable of conducting any case that may come under his especial care, no matter how serious it may be, for he will many times be so located that he can not obtain the advice of a consultant in his specialty; while, upon the other hand, he may be, and that frequently, called in by the post surgeon as a consultant in cases which present oral or dental lesions; or which by reason of certain symptoms the surgeon is led to believe may be dependent upon some obscure dental or oral malady, and upon which he desires an expert opinion to assist him in an intelligent treatment of the case.

ASSIGNMENT TO DUTY.

As rapidly as the candidates have passed the Examining Board they have been assigned to service in the Philippines and Cuba, for the reason that our troops located in tropical climates are in the greatest need of the services of the dentist. When these demands are satisfied in one location the dentist will be assigned to another station and thus moved about from place to place, wherever his services are most urgently needed. The number of dentists is so few, thirty in all, and the army so large, something over seventy thousand, that there is likely to be an abundance of employment for all those who enter this service. The opportunity, however, for a large and varied scientific and practical experience along professional lines, offered by the establishment of the Army Dental Corps, will be very great, and ought to prove a tempting inducement to the really progressive young man.

REGULATIONS GOVERNING THE DENTAL CORPS.

The following regulations having received the approval of the Honorable the Secretary of War, become, with the General Regulations bearing upon officers of the Army, the law governing contract dental surgeons:

Candidates for appointment as dental surgeons must be not less than 24 nor more than 40 years of age. They must be graduates of standard medical or dental colleges, trained in the several branches of dentistry, of good moral and professional character, and prior to appointment will be required to pass a satisfactory professional examination before a board of dental surgeons convened for that purpose by the Secretary of War.

Contracts with dental surgeons will be made for three years, but may be annulled at any time by the commanding general of a military department, after official investigation, for conduct to the prejudice of good order and military discipline, or by the Surgeon-General when in his opinion a termination of the contract would be in the interests of the service.

Dental surgeons are attached to the medical department and will be assigned to duty in accordance with the recommendations of the Surgeon-General of the Army or the chief surgeon of a military department.

A dental surgeon when assigned to a station will apply to the post commander for a suitable operating room. If no other room is available the surgeon of the post may assign him a room in the hospital.

Each dental surgeon will ordinarily be allowed one enlisted man as an assistant, who will be detailed from the acting hospital stewards or privates of the Hospital Corps, and whose duty it will be to assist the dentist in his operations, in caring for the instruments and other public property, in keeping the records, and in the performance of such other official work pertaining to this position as he may be directed by the proper authority to do. When a member of the Hospital Corps is detailed as dentist's assistant he will receive commutation of rations at the rate of $1 daily, and will be provided with a suitable room as quarters by the Quartermaster's Department, except while on duty at a post, when he will be attached to the Hospital Corps or other organization for rations and quarters. Necessary dental instruments and supplies will be purchased by medical supply officers under instructions from the Surgeon-General and in accordance with a supply table to be approved by the Secretary of War.

Dental surgeons will be held strictly responsible for all instruments and supplies issued to them and will be governed by army regulations and orders now in force, or hereafter to be issued, with reference to accountability for government property.

In accordance with the act of Congress authorizing their employment, dental surgeons will "serve the officers and enlisted men of the regular and volunteer army." The families of officers and civilian employees attached to the army are not entitled to their services. In this connection acting assistant surgeons are to be regarded as commissioned officers.

Dental surgeons will operate between the hours of 9 a. m. and 4 p. m. only upon those officers and enlisted men who are entitled to their services. They may operate upon others not entitled to free service before and after these hours when their services are not required by those entitled to them, but material issued to them by the Government will only be used in operations upon officers and enlisted men of the army.

Dental surgeons will not perform any operation upon officers or enlisted men of the army or prescribe medicines for them other than those necessary for the treatment of the teeth and gums. This prohibition does not apply to cases of emergency where no medical officer is within reach, and where a dental surgeon is able to render the necessary surgical assistance to meet the immediate emergency.

Emergency work, whether for officers or enlisted men, should always have precedence. Plate work or restoration of teeth by any method will only be done for those who have lost teeth in the service and in the line of duty. For plate work or filling teeth only the cheaper materials will be supplied, but gold may be used, if the operating dentist sees fit to use it, at the expense of the individual operated upon.

Enlisted men requiring the services of the dental surgeon will, at an hour prescribed by the commanding officer, be conducted to the designated place under a non-commissioned officer, who will take with him and hand to the dentist a list of those reporting for treatment. This list will be entered in a daybook ruled in columns for surname, given name, rank, company, regiment, etc.; all headings to be the same as those borne on his monthly report.

All cases requiring treatment involving future appointment will be so noted, and the others will be marked according to the circumstances, as "treatment unnecessary," "further treatment unnecessary," "should be sent to the surgeon," etc. When future treatment is necessary the dentist will forward a card as follows:

..........................19....

The Adjutant,

....

Sir:—I have the honor to ask that......................

be directed to report to me from ....m. to ....m. on ....

instant for treatment. Very respectfully,

....

Dental Surgeon.

Dental surgeons will submit a monthly report in duplicate (on prescribed blanks) of all official work done by them, giving all required data in every case in which professional services have been rendered. This report will be an exact copy of the register kept for the period. One copy will be sent on the last day of the month to the Surgeon-General and one to the chief surgeon of the department in which the dental surgeon is serving.

THE SUPPLY TABLE.

This table is too long to present in this place, but it may be stated that it includes a portable dental chair and a dental engine, packed in separate cases; burrs, mandrels, stones, discs, etc. Excavators, chisels, scales, plastic pluggers, gold pluggers, rubber-dam clamps, clamp forceps, dam punch, extracting forceps, elevators, steam sterilizer, etc., in fact all of the instruments and adjuncts that are really necessary to perform any operation upon the teeth, except for crowns and bridges. Each outfit contains medicines and supplies of filling material sufficient for three months' service. The smaller instruments and the supplies are packed in two strong cases, arranged with trays and receptacles to hold the instruments and supplies in place. The whole outfit when cased and crated weighs about 450 pounds. To protect the cases from rain and dampness they are enclosed in canvas covers. The general hospitals, and such other posts as may be designated by the Surgeon-General, will be furnished with an additional outfit, consisting of a regular office operating chair, Allan bracket, cuspidor, instrument case, extra extracting forceps, and a full laboratory outfit for constructing vulcanite plates, swaged metal plates, interdental splints, crowns and bridgework.

NOSOLOGICAL TABLE AND SYSTEM OF KEEPING RECORDS.

The ordinary system of keeping records in civil practice, by means of charts, could not be employed in military practice, for the reason that it would occupy too much space. As a substitute for this the following system has been devised and has received the approval of the Surgeon-General:

DISEASES AND INJURIES OF THE TEETH AND MOUTH.

Abrasion (mechanical).
Abscess of the jaws (associated with impacted teeth).
Calcification of the pulp.
Caries.
Cysts of the jaws (associated with devitalized teeth).
Dento-alveolar abscess.
Erosion (chemical).
Fractures of the teeth.
Hemorrhage (following extraction).
Hypertrophy of the pulp.
Hypertrophy of the gums.
Hypercementosis.
Necrosis of the teeth.
Pericementitis, acute.
Pericementitis, chronic.
Pulpitis, acute.
Pulpitis, chronic.
Pyorrhea alveolaris.
Resorption of the alveolar processes.
Salivary deposits.

Note: The duties of the dental surgeon will ordinarily be confined to the treatment of such cases as are directly associated with the teeth and gums; but occasions may arise when his services would be required as a specialist in the treatment of diseases and injuries of the mouth and jaws, such as cysts of the salivary ducts, empyema of the maxillary sinus, fractures of the jaws, gingivitis, necrosis of the jaws, facial neuralgia, stomatitis and tumors of the gums and jaws, etc.

CLASSIFICATION OF THE TEETH.

1. Superior Central Incisors.
2. Superior Lateral Incisors.
3. Superior Cuspids.
4. Superior 1st Bicuspids.
5. Superior 2nd Bicuspids.
6. Superior 1st Molars.
7. Superior 2nd Molars.
8. Superior 3rd Molars.
9. Inferior Central Incisors.
10. Inferior Lateral Incisors.
11. Inferior Cuspids.
12. Inferior 1st Bicuspids.
13. Inferior 2nd Bicuspids.
14. Inferior 1st Molars.
15. Inferior 2nd Molars.
16. Inferior 3rd Molars.

In designating the teeth, and in recording all operations upon them, the dental surgeon will indicate the tooth by the following plan, using the letters R. and L. to designate the right and left sides, and the figures 1, 2, 3, etc., to designate the tooth. Examples: R. 1, Right Superior Central Incisor; L. 14, Left Inferior First Molar.

CLASSIFICATION OF CAVITIES.

Simple cavities on exposed surfaces.

Incisors and Cuspids.	*Bicuspids and Molars.*
A. Labial.	D. Morsal.
B. Lingual.	E. Buccal.
C. Morsal.	F. Lingual.

Simple Approximate Cavities.

Incisors and Cuspids.	*Bicuspids and Molars.*
G. Mesial.	I. Mesial.
H. Distal.	J. Distal.

Compound Cavities.

Incisors and Cuspids.	*Bicuspids and Molars.*
K. Mesio-labial.	R. Mesio-morsal.
L. Disto-labial.	S. Disto-morsal.
M. Mesio-lingual.	T. Morso-buccal.
N. Disto-lingual.	U. Morso-lingual.
O. Mesio-morsal.	V. Mesio-disto-morsal.
P. Disto-morsal	W. Bucco-linguo-morsal.
Q. Mesio-disto-morsal.	

In recording all operations of filling the teeth, the cavity will be described by the dental surgeon according to the preceding classification, using the letters A, B, C, etc., to designate its location.

Example: A Simple cavity in labial surface of an incisor or cuspid tooth. I—Simple cavity in mesial surface of a bicuspid or a molar. V—Compound cavity in mesial, distal and morsal surfaces of a bicuspid or a molar.

Classification of Filling Materials.

Tin,
Amalgam,
Oxyphosphate,
Gutta-percha.

The kind of filling material employed will be indicated by using the first letter of the word designating that material.

Example: R. 5 Q. A. Tooth, right superior 2nd bicuspid; cavity, mesio-disto morsal surfaces. Filling material, amalgam. If a combination filling is employed it will be designated by the first letters of the words designating the materials used.

Example: L. 7. S. G.-O. Tooth, left superior 2nd molar; cavity, disto-morsal surfaces. Filling material, gutta-percha and oxyphosphate cement.

Exception: The only filling materials furnished for the use of the dental surgeon by the Medical Department are those enumerated above. Gold, however, may be provided by the dental surgeon and inserted for those officers and enlisted men who are willing to reimburse him for its cost. The minimum fee to be $1, and the maximum $2, for such filling.

In recording operations made with *gold* the full word should be written out.

Other operations upon the teeth will be designated by a combination of letters, as follows:

Abscess Lanced—A-L.
Calculus Removed—C-R.
Pulp Devitalized—P-D.
Pulp Extirpated—P-E.
Root-canal Filled—R-F.
Tooth Extracted—T-E.
Tooth Treated—T-T.

One hundred of these record sheets are bound in a book, and form the Register of Dental Operations. Each month the dental surgeon is required to send to the Surgeon-General an exact transcript of the Register of the operations performed during that month, upon blank sheets known as the Monthly Record of Dental Operations. These reports are placed on file for future reference. The Register when filled is transmitted to the Surgeon-General and also placed on file.

These records will form an important means of identification in casec of death or desertion, while to the Pension Office they will prove of value in passing upon those applications for pension which are based upon the loss of teeth while in the service of the United States Army.

They will also prove to be of immense value from the scientific standpoint, in efforts to settle the questions of the relative prevalence and spread of dental caries among men who have been selected for military service, because of their perfect physical condition; as compared with men in civil life. Of the relative increase in this disease resulting from physical and nervous strain of severe campaigns, and of residence in tropical climates. Of the causes and prevalence of pyorrhea alveolaris, gingivitis, stomatitis, and kindred oral affections.

It will be noticed by the Regulations governing the Army Dental Surgeons and the rules laid down by the Surgeon-General, that the only filling materials which will be furnished by the government are tin and the *plastics;* but the dentist is not prohibited from using gold, if the officer or the enlisted man is willing to reimburse him for the material used. (This material he must carry with him at his own risk.) In fact, he is encouraged to use gold by being furnished with instruments and appliances with which to perform this class of operations. He is, furthermore, furnished with an acting hospital steward, whom he is expected to train as an assistant. With such intelligent assistance as this, there is no reason why as good gold fillings may not be inserted by the military dental surgeon as by the dentist in civil practice.

The character of the service which must be rendered in the field, will of necessity be that of meeting emergencies. Relief from suffering will be the first object of the treatment, and the introduction of temporary fillings to protect the teeth from further decay until a more favorable opportunity can be secured for inserting a permanent filling.

The dental surgeon will, however, as a rule, be located at posts and stations of a more or less permanent character, where he can conduct his practice with as much care and thoroughness as is possible with the civil dental surgeon.

Each field outfit is provided with a quantity of modeling composition and impression trays, so that fractures of the maxilla can be treated temporarily by interdental supports made from the modeling composition, while the patient is being transported to the general hospital, where facilities will be found for constructing any form of interdental splint or other mechanical apparatus that might be indicated.

The army dental surgeon is expected to confine his professional services to the treatment of the diseases of the teeth and their associated parts, but the regulations provide that in cases of emergency, when no surgeon is present, he may, if competent, render any assistance that the case may demand.

The dental surgeons located at general hospitals and large posts will be furnished with as good and as complete an outfit for a general dental practice as is found in the offices of the best civil practitioners. At such stations the dental surgeon will have frequent opportunities for the treatment of cases in orthodontia for the children of the officers of the station, or inserting crowns, bridges, and artificial dentures, for the officers and enlisted men, and for their families; while the general hospitals will furnish a certain number of cases of fractured maxilla, that will need to be treated by the construction and insertion of some one of the various forms of interdental splints.

From the foregoing pages it will be seen that the War Department, through the recommendations of the Surgeon-General, has provided for the care and the treatment of the dental and oral diseases of the Army in as thorough and as scientific a manner as is possible under the exigencies of military life and movements. Experience, however, may make it necessary to institute certain changes and modifications in the present system of service, and when such action is proved to be essential to the welfare of the army and an increased efficiency of the Corps, there is no doubt but that the proper authorities will immediately institute such changes and modifications.

DISCUSSION ON MILITARY DENTAL PRACTICE.

Dr. A. E. Baldwin, Chicago—I have been very much interested in this branch of our professional world ever since the talk of its organization in the army has been before us, and especially have I been interested the past year when active steps have been taken towards carrying out this plan. I was pleased with Dr. Hatch's presentation of the subject, and I am much pleased with the discussion, or rather the supplemental paper, given us by Dr. Marshall in connection with this. I feel and have felt from the beginning that the profession at large would be very well represented, in fact, better represented by Dr. Marshall on that Board as an organizer of this branch of army life than any man I know. I have known him for a great many years and sat under his instruction years ago as a student. I have never seen a man who would grasp, arrange and organize matters in the minutest details like Dr. Marshall, which is shown in this paper. I think the army is to be congratulated, and especially the surgeon-general upon having such a man in his department; I shall look with a great deal of interest for the results of this work.

Dr. Charles Chittenden, Madison, Wis.—As an examiner of a number of years' experience, it seems to me it would have been impossible at the first attempt for any Board to have laid out a more practical, complete scheme than that presented here to-day. It fills me with admiration and delight. It is a movement in the direction that shows that such men in our profession as have been put into prominence in this way are equal to the occasion. It makes me proud of the fact that we have got such men. I think we are to be congratulated upon the work of this Board as far as it has been carried on.

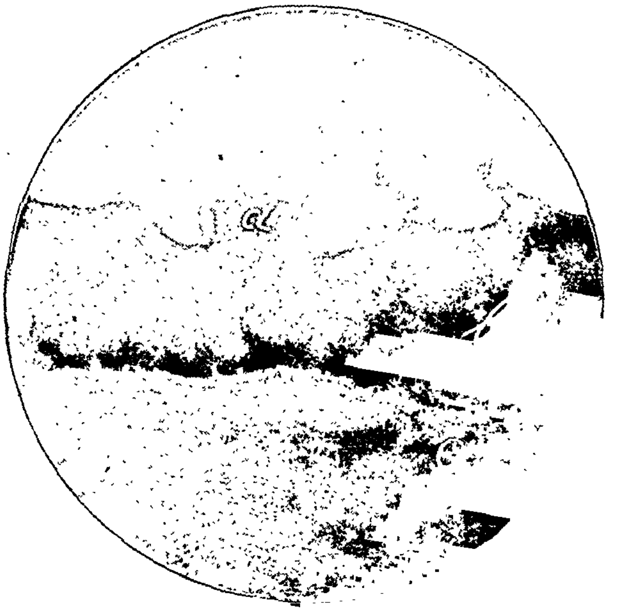
Dr. Eugene S. Talbot, Chicago—It occurred to me after that bill was passed that the profession knew very little about the work to be done by the dentist appointed to fill the position in America's new possessions. It is very gratifying to know that Dr. Marshall has received that appointment. The fact that so few men have been appointed or accepted who have applied, augurs well for the standard the Board has adopted. They have already stirred up quite a little commotion in dental journals. Editorials have been written in dental journals and letters have been received showing there is uneasiness. The average dental teacher is of the opinion that all there is of dentistry is simply the filling and extraction of teeth. It is very fortunate for education of the profession that this law has been passed and a number of dentists sent to the field to attend to soldiers. The work of filling teeth is a very small part of the work these dentists are called upon to perform. It has been shown not only in Cuba, but in the Philippines that many diseases, especially gingivitis, affect the jaws of people who suddenly change climate. It is due to the manner the excretory organs are affected by the sudden change of climate, the jaws and teeth become involved, and in a very short time, sometimes in the course of a few weeks, inflammation sets in, the teeth become loose and in many cases drop out. Such conditions appear in the report that Dr. Marshall has made. The fact that a dentist is expected not only to fill teeth and make plates but to perform other duties, ordinarily within the scope of a physician or surgeon, demands that dentists be properly educated along these lines. The average physician has to be posted in the treatment of those apparently new diseases. A man to treat these cases intelligently must understand general medicine. Just how far a dentist would be allowed the conduct of these cases and give treatment remains to be seen. The conditions shown by Dr. Marshall makes it evident that dental colleges will have to advance their course in pathology and that a four years' course is now necessary.

THE TONGUE AS A BREEDING PLACE FOR BACTERIA.*

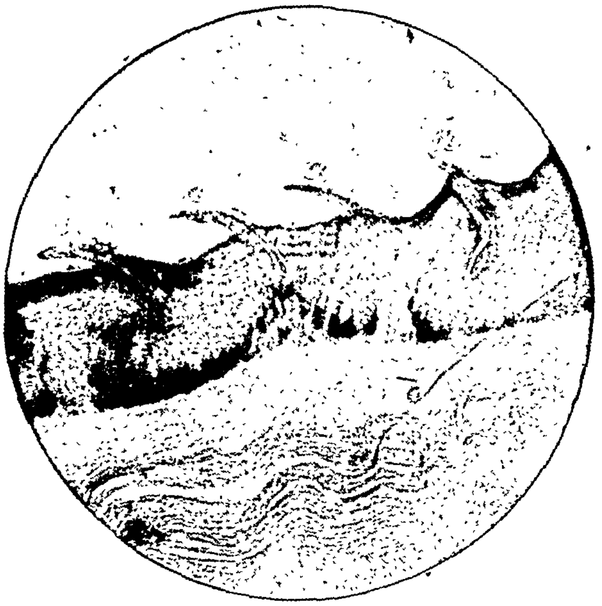
H. M. FLETCHER, D.D.S., M.D., M.S.
CINCINNATI, OHIO.

The accompanying photomicrographs of sections of the human tongue show it to be covered with glands, fissures, and spinous processes, the latter slanting at a great angle. It is evident that this surface may hold pabulum and protection for the development and growth of myriads of bacteria. It is possible that cavities in the teeth, and gums diseased from deposits about the teeth, are more prolific, but probably not.

Out of the "seven nutrient media for bacteria in the oral cavity" given by Miller, five are always present on a coated tongue, namely, normal saliva, buccal mucus, dead epithelium, particles of food, and exudations from diseased gums.



Section of Human Tongue.—X 75. aaa, Filiform papillæ; b, mucous membrane; c, muscular tissue; d, circumvolate gland.



aaa, Filiform papillæ; b, mucous membrane; c, muscular tissue.

Formerly physicians were very careful about the examination of the tongue, but at present the diagnostic value of its coating is largely disputed. On the other hand, some of the best physicians make the tongue the principal basis of their diagnosis, especially in gastrointestinal troubles. But the tongue as a breeding place for bacteria is properly attracting more attention at present and cannot justly be ignored.

Van Valzah-Nesbet has said: "The tongue is not a mirror of the stomach, as the ancients supposed, but is a local mirror which reflects only that which comes over its surface."

Dr. A. L. Russell says: "The color is due to the pearly color of the cornified epithelial cells covering the papillæ; to retained particles of food, and the debris of microorganisms, broken down epithelium and mucus. The color of the organ proper is quite as important as its motions, contour, lesions and coating. It is well to remember that in perfect health there is usually a slight, uniform coating of a whitish color diffused over the entire tongue, and that towards the base of the tongue in the region of the circumvallate papillæ there is always a heavy coating, which is increased with any increase of the normal coating of the anterior portions."

Hare says: "The coating may be black from the ingestion of iron, charcoal, bismuth, ink, berries, cherries, or red wine. It may be stained brown from tobacco, licorice, nuts, prunes or chocolate. It may be yellow from the ingestion of rhubarb or laudanum."

F. Forcheimer says: "In some cases the tongue is of great clinical importance and in many others its examination for diagnostic purposes is without value. It goes without saying that no case has been completely examined unless the mouth has been looked into, and yet in a great many cases nothing is gained by this examination. . . . The tongue is affected as the result of local and general conditions. . . . The changes that take place are in the direction of size, shape, color, coating or fur. The blood affects the color of the tongue, as a whole, more than any other cause. The furring of the tongue is that portion of our subject which has been most studied. The fur upon the tongue is, when examined microscopically, seen to be made up of epithelial cells, molecular detritus, and organisms of various kinds, held together by mucus. The organisms are those usually found in the mouth; sometimes we find pathogenic organisms, most frequently the pneumococcus and pus producers. In long-continued fevers, in which the absence of moisture is the predominating cause, we have a peculiar condition of a dry white fur, quite thick and adherent. When there is not sufficient movement of the tongue there results a fur, because fewer of the old cells are removed than would be under normal circumstances. In paralytics we constantly see a furred tongue. The place of deposit of this fur depends very much upon the size and shape of the tongue; where the tongue does not come in contact with other parts of the mouth it will be thick, at the edge it will be rubbed off, leaving a red outline. The most ludicrous mistakes occur to those who overlook the fact that particles of food and medicinal agents give their color to the fur; rhubarb produces a beautiful liver tongue."

---

* Read in the Section on Stomatology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

The concensus of opinion of the foregoing investigators seems to be that the coatings of the tongue are local and not indicative of any particular disease, and that the mass contains large quantities of bacteria. These coatings may be accounted for as follows:

The dorsum of the tongue, with its processes, glands, fissures and rough, horny surface is most favorably constructed for holding detritus from its own surface and from other parts of the mouth, also small particles of food and tartar; but the great factor of the formation and persistence of this coating is mucus. The coating forms at times into almost a membrane. This is due to the cementing qualities and the insolubility of the mucus discharged into the mouth.

The easily and quickly forming cakes of mucus in the nostrils is accounted for by the continuous passage of air over its surface, drying it rapidly, carrying dust and foreign matter into its substance which becomes imbedded, producing black, yellow, gray, or other color, dependent upon the character of foreign particles with which the air is freighted. The surface exposed to the air becomes hardest; that next to the membrane is softer. When the mucus finally dries and shrinks, it breaks into patches. curls and drops away, or is removed.

The mucus of the mouth, when separated from the more fluid portions of the saliva, is just as strong a cementing agent as that of the nostrils, and holds the particles of food, dead epithelial cells and tartar into a mass or layer, covering the rough surface of the tongue, also cementing the coating to the slanting, filiform processes. and to the uneven surface. Under this layer the mucus is continually secreted, and the desquamation of epithelium goes on; thus the layer is continuously added to from below as well as from above.

The upper surface of the layer being constantly wet has no opportunity to become dry and break up into patches as in the nose. In persistent mouth breathing it may occur, or portions of the coating may be removed mechanically, producing what is called "patchy tongue." Mouth breathing rapidly drives the water from the saliva, leaving the mucus and causing it to stick the closer and make the layer thicker and more persistent.

Such systemic disorders as tend to produce fever have their effect upon the mucous membrane, among the first of which is the "dry stage." In this stage the mucus is thicker, less abundant and dries quicker. This is as true of the dorsum of the tongue as of any other mucous membrane, hence the coating is usually pronounced and well formed by the time the physician is called to see the patient.

The color of the coating is largely effected by the incorporation of blood from different parts of the mouth, most frequently from bleeding gums, a condition found in a large percentage of people at all times, or it may be colored from many sources as cited, and not unfrequently from bacteria. Miller has cultivated a number of chromatic mouth-bacteria.

In addition to personal observation the foregoing would seem strong evidence to convince one that the coatings of the tongue are from local causes, but may be favored and increased by febrile conditions which precede or accompany almost every bodily ailment. Lack of cleanliness and mouth breathing are undoubted and prolific causes.

The danger from unclean tongues and mouths containing decayed teeth and diseased gums are graphically set forth by Miller. He says: "From a neglected mouth, such as repeatedly comes under the observation of dentists, enormous quantities of bacteria must reach the intestinal tract, in spite of the sterilization of food. In a very unclean mouth examined for this purpose I estimated by culture methods the number of cultivatable bacteria at 1,140,000,000; many of them were doubtless carried to the stomach during every meal, to be replaced by others developed between meals and over night."

Von Kaczorowiski proves clearly enough that the micro-organisms in an unclean mouth, quite independent of those introduced with the food and drink, suffice to produce intense fermentive processes, chronic dyspepsia, etc.

Even with decayed teeth and diseased gums to breed bacteria in great numbers, the dorsum of the tongue still presents the largest surface for their growth; and if it is not cleaned once or twice a day (which practically no one does) it is one of the greatest of all places in the mouth for breeding bacteria.

The mucus which cements the layer of sordes upon the tongue and lips is not soluble in water, ether, alcohol, chloroform, or dilute mineral acids, but is soluble in alkaline solutions, and since nearly all of our food is either acid or neutral, and not one in thousands thinks of scrubbing the tongue as a matter of cleanliness and protection, it certainly is a source of danger and infection, and an undoubted condition for perpetuating disease, especially with invalids.

In order to test the solubility of mucus in alkaline solutions, try scrubbing the tongue with a toothbrush filled with powdered biborate or bicarbonate of soda, and notice how the coat disappears. (Biborate is the least disagreeable.) Protrude the tongue and scrub it from back to front until the coating is removed. When the tongue is to be examined for diagnostic purposes this should be done so that the real color and condition of the tongue can be examined. Then the diagnostic features will be visible and of undoubted value. The use of the brush is much better than to scrape the tongue with a hard instrument. Ordinary tooth powders are not satisfactory because the finely pulverized chalk or other earthy matter remains on the tongue like food and dead epithelium, and the real condition and color of the surface is still unexposed for inspection. Coarse powdered borax or cornmeal, or the two mixed, form a coarse detergent powder very efficient for this purpose, as well as for cleaning the teeth and gums.

A clean mouth undoubtedly prevents much fermentive and putrefactive indigestion, not to mention its comfort and the prevention of tooth decay and diseased gums.

Animals keep deposits from the tongue by its use as a prehensile organ, and by licking their bodies and other substances. Then the saliva of animals in their native state is decidedly alkaline in reaction, and keeps the mucus dissolved much better than does the human saliva. The latter is either acid or very weak in alkaline reaction, a condition accompanying civilized life, and may be found in animals kept as pets or in confinement and fed upon prepared foods.

There is probably no way of estimating the great immunity brought about by keeping the mouth and all it contains perfectly clean. As a prophylactic measure no physician can afford to neglect it, either for himself or his patients.

DISCUSSION ON PAPER OF DR. FLETCHER.

DR. EUGENE S. TALBOT, Chicago—I differ with the essayist in regard to the cause of the coating of the tongue.

Dr. Kiernan, in his paper yesterday, alluded to the alimentary canal in the development of the child. He pointed out that the alimentary canal and rectum were structures completed later in development; that is, that other structures of the body were perfectly developed before the alimentary canal and rectum. That is precisely the condition I have noticed in children. As shown the condition results from this abnormal state of the alimentary canal. This condition called indigestion is very common among neurotic and degenerate children. Neither neurologists or clinicians view it as a local condition. I believe that probably food is taken by the child which does not assimilate in the alimentary canal; hence, the small intestine does not perform its function and markedly furred tongue results. I have frequently seen this condition occur as often as four times yearly in a child. While food has a good deal to do with it, the assimilative and excretory organs do not harmonize in their action and constipation results. I do agree with Dr. Fletcher in regard to the treatment of these conditions. Local treatment will help greatly in clearing up the tongue, especially after the alimentary canal has been put in normal condition. Scraping the tongue may be done well, either with an instrument made for the purpose or with a stiff tooth-brush. Stimulation has most to do with the results. Frequent clearing up of the tongue results after brushing and stimulating it into a healthy condition.

Dr. G. V. I. Brown, Milwaukee, Wis.—It seems to me the essayist has given us a partial proof. What he says concerning the effects of mouth-breathing upon the mucous membrane of the tongue is true in a measure, but if it were entirely true I think we would notice greater changes in the structure of that membrane in patients who are chronic mouth-breathers. While there are quite small changes in the mucous membrane, particularly in the nasal passages, that of the mouth is not materially altered, so far as its permanent form is concerned. I think you all know that I am rather partial to the use of hydrogen dioxid to prepare the mucous membrane for the action of the antiseptic which you are going to use. You may not depend upon the dioxid as an antiseptic *per se*, but there can be no difference of opinion as to the value of preparing the mucous membrane by using that and then following with any germicide solution. In the treatment of patients with cleft palate and other operations of the mouth, the cleansing of the mouth every half-hour, in addition to repeated washing through the nose, perhaps once or twice a day, is a matter of vital importance, and is beneficial in two different ways: One is that the effect of the germicide used is constructive to the mucous membrane, and serves on the other hand to destroy the poisonous effects of the use of the germicide which is of a nature to be destructive upon living tissue of any kind, so I have come to use the dioxid, a 3 per cent. solution, and carbolic acid alternately, using one each half-hour, and getting good results in that way.

Dr. A. E. Baldwin, Chicago—I have little to say, only that I was glad to listen to the paper, and it shows a line of investigation that could be made productive of results. I have long thought that the mucous membrane of the mouth is perhaps more pathognomonic than we have given it credit for, but how far the investigation, as given in the paper, turns that way, I am not prepared to say. I have in a quiet way followed the investigation as carefully as possible in the mucous membrane of the mouths of my patients, observing them very carefully, but so far I have obtained no results that I feel would be proper to present before this Section.

Duration of Pregnancy.—According to the German laws the maximum duration of pregnancy is estimated at 302 days. Winckel has been reviewing the statistics of the Dresden and Munich maternities and finds that 1007 children are recorded among the 30,500 births during the last thirty years, who measured 48 to 52 cm. in length and weighed 4000 gm. Of this number 233 or .4 per cent. were born after the pregnancy had lasted from 303 to 336 days, showing that in case of unusually large children the duration of the pregnancy is longer than the laws admit. He mentions that none of the children ever weighed as much as 6 kg. at birth, and none at Dresden during the last eleven years weighed even 5 kg.—*Sammlung Klin. Vortraege*, 292.

A CONTRIBUTION TO THE SURGERY OF THE KIDNEY.

TWO CASES OF DISEASE OF THE KIDNEY SIMULATING GALL-STONES.*

BAYARD HOLMES, M.D.
Professor of Surgery in the University of Illinois; Surgeon to the Baptist Hospital.
CHICAGO.

The surgery of the kidney is much neglected in general practice on account of the difficulties of diagnosis which the surgical diseases of this organ present. The organ itself is hidden in the back. Its exploration through a mid-abdominal incision is unsatisfactory. The urine does not always present a suggestion of the condition of the kidney. The symptoms often lead the physician astray. Two such cases in my own practice seem to me worthy of record as a warning.

When we approach any diseased abdomen, our attention is fixed more or less intently on certain luminous spots, toward one or more of which the symptoms course or the findings almost inevitably point. The spots are the appendix, the gall-bladder, the pylorus, the kidneys and the appendages of the uterus. When we analyze the symptoms and findings of typical cases, there is little danger of error, but in atypical cases, such as the two which I have chosen to present, the diagnosis is very uncertain even after the closest observation. I hope that you will not be wearied by this simple method of presentation, for I have always found the recital of well-studied cases of the greatest practical value.

Mrs. C., 35 years old, was born in New England and educated in one of the colleges for women. She had no sickness of any account during her childhood, but as adolescence came on, she had painful menstruation and became rather nervous and hyperesthetic, but not to any serious extent. After graduation she went to the Sandwich Islands to teach. She married there and returned to the States, where a child was born in 1895. This confinement took place in Philadelphia under competent assistance, but there is evidence in the history there was some puerperal infection of a low grade, which persisted a rather long time. After the confinement, at intervals of two or three months and rarely at intervals of ten days or two weeks, the patient suffered attacks of abdominal pain accompanied by considerable rise of temperature and rarely by vomiting. These attacks lasted only a few hours each time. The pain began in the pyloric region and extended through the back and both shoulders. There was tenderness under McBurney's point during one of the attacks, and a diagnosis of appendicitis was made. In one of the attacks a tumor was felt in the same region, and this time a diagnosis of wandering kidney was made by another physician. After these attacks there was a gradually falling temperature and considerable prostration. The patient had been put on a restricted diet without effect. She had tried hydropathic treatment and a vegetarian diet without any modification in the frequency or the severity of the attacks.

In June, 1899, she left the Sandwich Islands and came to Chicago under my treatment. I found the patient a very intellectual woman of nervous, sanguine temperament and a New England conscience. She weighed 125 pounds. Her history was given clearly, explicitly and without bias. On examination, I found a perfectly developed chest and normal heart and lungs. The apex-beat, however, was three inches from the middle line, indicating a moderate enlargement. The blood showed a normal proportion of red and white corpuscles, but the hemoglobin was only 65 per cent. Malarial organisms were found in abundance. There were many floating black particles in the blood, of unknown significance. The urine was slightly diminished in quantity and in normal constituents—18 to 22 grams of urea a day—but although frequent examinations were made, there were never any abnormal constituents found. In examining the abdomen, both with and without chloroform anesthesia, no tumor nor abnormality was discovered.

---

* *Read before the Tri-State Medical Society, April 4, 1901.*

The patient was put on antimalarial treatment, consisting of mild laxatives, a light diet, large doses of quinin, 20 grains six hours before the appearance of the slight rise of temperature, 99.5 F., followed by arsenic for two weeks. This rise was discovered by taking the temperature every half hour during waking hours. The organisms were gone by the end of a week. During the next few months the blood was repeatedly examined, but no malarial organisms again discovered. The hemoglobin rose gradually to 85 per cent.

There were no attacks of pain during the first few weeks she was under my care, but one morning at the end of two months she sent for me in great haste, and I found her suffering moderately from pain in the abdomen, back and shoulders. Her temperature was only 99 F., the pulse moderately accelerated. The patient was not anxious or fearful and willingly allowed protracted examination before morphin was given. Now for the first time a tumor in the region of the gall-bladder was easily outlined. It was not movable, but clung to the lower border of the liver and moved with each inspiration and expiration. It was moderately tender on pressure. No other signs or symptoms were elicited. A small hypodermic of morphin was given and the hot water-bag placed over the liver. In two hours the pain and tumor had both disappeared. The next attack came on only a few days later, after a hearty meal. It resembled the first attack in every particular, except that it began with vomiting. The tumor appeared again and disappeared with a liquid movement of the bowels. The third attack came on in October, and was more severe and long lasting than either of the others. This time I had Dr. George W. Webster in consultation. He saw the patient alone. The tumor in the region of the gall-bladder was present as before, but now for the first time there was distinct jaundice and the urine contained an unmistakable circle of bile. The case was thought from the first to be one of stone in the cystic duct, for the following reasons: 1, pain in the region of the back and shoulders; 2, tumor in the region of the gall-bladder; 3, absence of all evidence of renal disease; 4, clinical history of biliary calculus. With this history and the advice of Dr. Webster, I deemed it best to remove the stone.

After the usual preparations and under chloroform anesthesia, she was operated on November 30. Her temperature was normal and her pulse 88 before the operation. An incision three inches long was made along the right border of the rectus muscle and the abdomen explored. The gall-bladder was of normal appearance and thickness and contained no calculus. The right renal region was filled by a cyst-like mass somewhat larger than a kidney. The ureter was of normal size and feeling. The peritoneum was opened over the kidney and behind the colon and attached to the depressed peritoneal edges of the abdominal wound by continuous and by interrupted catgut sutures. The small amount of fat over the cyst was pushed away and the tumor pulled out through the abdominal wound and examined. It was found to be a cystic kidney, the outer surface of which looked like an ovarian cyst. The kidney substance was gone, except at a point near the lower pole, where a mass remained as big as the ball of the thumb. The wound was protected and the cyst opened. It was found to involve all the calices and the pelvis. The ureter opened out of it by a short turn. There appeared to me no way by which the small amount of kidney tissue could be saved and the ureter made effective. Therefore the artery and veins were separated from the ureter and ligated with strong, braided silk. The kidney was removed and the ureter pulled out of the wound as far as possible and cut off. The mucous membrane was turned in and the muscular and fibrous coats sewed tight together with fine silk. The stump was then dropped. On account of fear of infection from the interior of the cystic kidney which had been opened over the wound, I decided to pack the cavity with gauze containing a little iodoform. The ends of the abdominal wound were closed, leaving only a small opening for drainage. The operation lasted an hour and a half and was borne without event.

The temperature rose four hours after the operation to 99.6 F., and there was considerable pain and vomiting. During the following few days the urine was quite scanty, but it contained no abnormal constituents. The temperature never rose above 100 F. and the convalescence was perfectly normal. The packing was removed from the wound within a week, but the cavity became infected and did not close until six weeks later. Warning was given by a sharp chill and rise of temperature to 104 F., and the silk ligature on the renal artery was removed under cocain anesthesia. The urine had gradually and steadily increased in quantity until it reached 1000 c.c., and until the urea rose to 18 to 20 grams a day. During the convalescence there was a sharp attack of pain resembling the old paroxysms, but since that time, almost a year and a half, she has had no pain and no sickness. The urea has steadily increased and the patient has enjoyed almost perfect health. She has led an active student and literary life.

Mrs. M., 40 years old, of New England stock, was born and spent most of her early life in the tropics. She was always very active mentally and physically, but was never very strong. She weighed about 120 pounds. She was never ill except when her only child was born eight years ago. The labor was difficult.

In 1889 she had an attack of colic with fever and jaundice and was ill several days. Again, a few years later, while in Europe, she had a somewhat similar attack without jaundice. In 1898 she had several attacks of severe pain in the abdomen. During these attacks I attended her. The pain was severe paroxysmal, lasting fifteen to thirty seconds, with about an equal interval. She preferred a sitting position, bent over on her knees, with head and shoulders turned down. The greatest pain was in the back and shoulders, with none in the legs or vulva. The muscles on the right side of the abdomen were rigid and examination was difficult. A few drops of chloroform in olive-oil usually relieved the pain at once. On a number of occasions she had the sudden relief characteristic of displaced mechanical obstruction. The urine was frequently examined, but no abnormal constituents were found. There was no bile. A provisional diagnosis of gall-stones was made. The patient without any recommendation took the olive-oil treatment. There was a long interval, several months, of apparent relief, but during this time she always remembered her side. About October, 1900, she was taken with a most severe attack and for the first time a distinct tumor was felt in the region of the gall-bladder. It was hard, round, immovable and painful. A few whiffs of chloroform were given to facilitate examination, and after waking up the pain was gone. The next day the tumor could not be felt. During the Christmas vacation a very protracted attack was suffered and this time there was no complete relief for a week. Severe sharp attacks followed in quick succession after her return to the city, and in two or three, the tumor in the region of the gall-bladder was unmistakably felt. In one attack, the pain disappeared during palpation of the abdomen. Her temperature during these paroxysms rose to 99 F., but once or twice a degree higher. The urine was uniformly acid, of rather large quantity and contained 2.5 to 3 per cent. of urea. There were never any abnormal constituents.

With the following indications and diagnosis, which I copy *verbatim* from the notes of her history sheet made before operation, she entered the Baptist Hospital for operation Jan. 14, 1901.

INDICATIONS AND SYMPTOMS.

1. History of abdominal pain, region of gall-bladder, radiating into back (and shoulders), certainly not into labia or legs. Duration six or eight years.
2. These pains severe, often light or simply threatening; when severe, terminating suddenly with complete relief.
3. Rigidity of muscles over right side of abdomen continuing even after the paroxysms of pain have subsided.
4. Tumor felt on at least three separate occasions in region of gall-bladder. Unfortunately no history or record of recognition of kidney at same time and separate from it.
5. No tumor or tenderness over appendix or over course of ureter, or in pelvis.
6. No tumor or tenderness over pancreas.
7. No tympanites. Rumbling of gas in bowels during and after attack, with no appreciable relief from pain or difference in character after paroxysm.
8. No fluid in peritoneal cavity.
9. No abnormal constituents in urine; acid.
10. No dilatation or hypertrophy of heart as in stone in kidney.
11. No evidence of tuberculosis in examination or history.
12. Low temperature, 99 to 100; with subnormal temperature of 97.5.
13. No vomiting, and only once or twice "sick headache."
14. No disorders of bowels, movements a little tardy, no diarrhea after paroxysm.
15. No jaundice (except in 1889).

DIAGNOSIS.

The diagnosis lies between 1, gall-bladder disease; 2, appendicitis; 3, mechanical obstruction of kidney; 4, tubercular peritonitis; 5, obstruction at hepatic flexion of colon; 6, tumor in this region; and lastly, gatralgia or hysteria.

The disease or condition is of long duration, 2 to 8 years; no suppuration, temperature 99 to 100; probably mechanical, stopping the discharge of some viscus and the peristaltic action of some set of muscles.

The usual preparations were made and with chloroform anesthesia the abdomen was opened on the right border of the rectus muscle. The gall-bladder was found empty of stone and normal in appearance. The right kidney was movable and directly under the gall-bladder, but easily brought into the middle-line under the umbilicus. After thorough examination of the pylorus, the appendix and the right ovary, the floating kidney was considered the only adequate cause of pain; it was fastened back in its place in the usual manner. The location was approached by a long, curved incision, the kidney denuded of fat and pushed back so as to button through the inner fascia of the quadratus. It was fastened to the fascia by a double row of interrupted long-lasting catgut stitches. Both wounds were then closed in layers.

The patient made a perfect recovery except for one alarming complication. During the four weeks she was in the hospital, she had three attacks of pain similar to the pain she formerly suffered. Since that time she has been entirely free from pain. The kidney remains in place and she has resumed her very active life.

THE GYNECOLOGICAL AND OBSTETRICAL SIGNIFICANCE OF GIRLHOOD.

HENRY P. NEWMAN, A.M., M.D.,
CHICAGO.

I have recently received a letter from Dr. George Engelmann, of Boston, announcing his intention of reading a paper before the Gynecological and Obstetrical Section at the June meeting of the Americal Medical Association, on "The Causes of the Increasing Sterility of American Women," and stating his conviction that the subject is of vital importance and needs investigating. The same authority, as President of the American Gynecological Society, made an elaborate address last year upon a very nearly related topic: "The American Girl of To-day," and aroused much interest in his carefully prepared and somewhat startling statistics. It would appear from his researches, and in these he was assisted by prominent educators, teachers in young women's colleges and normal schools and by the heads of mercantile houses where women are employed, that the absolutely normal, healthy girl is exceedingly rare. It is evident that for her own sake as a future mother and for the sake of the race which is to come of her that we should do something to better the conditions which threaten her maternal functions.

The lack of fertility is not the only evil. The need is not so much for larger as for better families. The higher you go in the scale of animal value and intelligence the scarcer become the progeny. We want a better physical heritage for the few. It is the right of each individual to be perfectly born and generously nourished at a healthy mother's breast. A perfectly just and apparently simple proposition, but one requiring the united effort of our entire domestic, social and scientific systems. It has been proposed that the obstetrician be given charge of the whole period of gestation. But this is not enough. Too often he will find threatening lesions, infections, inflammations, malformations and malpositions already existing and will feel that to be successful with his case he should have had an oversight over the years of girlhood in which so much mischief was done.

The case-books of our specialists in gynecology and obstetrics and the records of teachers and employers of young girls go to show that the period between childhood and womanhood is not all what it should be. This period in which nature is concentrating all her energies upon the development of the generative organs and the establishment of their physiological functions is ordinarily that in which greatest demand is made upon the vital forces of the girl by the exigencies of our modern social and educational systems.

Her mental and nervous forces are taxed to the utmost by the ambitions of the study room, and the transitions from grammar to high and normal schools; she is overworked by the addition of music and one or two languages to the already full curriculum of the class; her digestion is impaired by that wretched institution the school "lunch," and other abuses; her muscular activities are curtailed by the adoption of the corset and a more mature and burdensome form of dress; her social instincts are roused by too early participation in exciting amusements, and with it all she begins to experience the nerve-trying influence of the menstrual epoch. If employed as a wage-earner the conditions of her occupation are even less favorable in the majority of cases. Under these complex and unhealthy stimuli the average young woman may present a bright and vivacious appearance but is wanting in endurance, nerve-force and general physical tone. In a very large percentage of American girls there is greater or less impairment of the menstrual function. Engelmann's statistics, covering all degrees of pain, give as high as 73 per cent. of suffering at the monthly period, and 50 per cent. of irregularities of all kinds. Not all of these young girls consider themselves, or are to be classed, as invalid, but it may certainly be affirmed that all deviation from the physiologic in the performance of the menstrual function is a detriment to the function of maternity in the same degree as the woman has departed from normal standards. As I have observed in numbers of cases the sequence is this: irregular menstruation, seldom profuse or prolonged but usually accompanied by pain at the beginning and during the progress of the flow. After a varying lapse of time, this characteristic menstrual pain is preceded by a prodromal stage of nervous exacerbation in anticipation of the flow and due to the gradual development of congestive or structural disease of the ovaries. Sometimes this goes on to a condition of pronounced or partial invalidism; sometimes the patient, and I use the term advisedly, for about this time the unfortunate pathology is brought to the attention of the physician, sometimes the patient marries. If married, such a woman may expect either total sterility or the birth under most unfavorable circumstances of one or two children. Sometimes she loses her life; often through unavoidable obstetrical accident, her little remaining health; sometimes her child is sacrificed, and all to the Moloch of our bad social and educational methods. To quote Engelmann's words: "The girl pays the penalty and the community suffers." To return to the etiology and pathology: the disturbance of the process of development of the generative organs, which is the chief concern of Nature in the pubertal period, the forced activity of other organs through misdirected or ill-timed educational methods results in a thwarting of the growth in the pelvic regions and a condition there which is pathognomonic. In gynecologic parlance we speak of it as infantile uterus, or the puerile or juvenile cervix according to the degree of arrest of development. In the first the process of development has been nipped quite in the bud, while in the latter and commoner form Nature's efforts have been fairly successful as to the corpus uteri while the cervix remains long, conical and deficient in lumen.

This typical maldevelopment of the cervix plays a disastrous role in the future history of the woman. Pain itself, not always pronounced in the beginning, gradually becomes a feature of the moment. Recurring monthly this influence is baneful and like all chronic suffering, exhausting and devitalizing. The congestion incident to this state of things becomes more persistent as time goes on until a passive congested state is continuous throughout the intermenstrual period. There is general lowered vitality and less resisting power, so that even should pronounced infection with inflammatory exudates be wanting, a low form of white-cell proliferation occurs and the newly-formed connective tissue hardens, contracts and, by constricting the lumen of the cervical canal, renders this important organ unfit to perform its functions, softening and dilating in menstruation, copulation, and childbirth, drainage of the uterine cavity, etc. The ideal handling of these cases is prophylactic, such as is embodied in that trite advice that we begin with the girl's grandmother. Being forced to make our beginnings with this generation we must do the best we can for it. Much can be done by instructing mothers in the management of the maturing child. Perfect confidence between mother and daughter will insure hearty co-operation on the part of the latter in all efforts for her developing health and strength. Out-door life should be rigidly insisted on for the girl as for the boy. The dress should be as free and unconfined as his. Forced mental development at the expense of the physical should be discouraged. In fact, due observance should be given to the hygiene and sleep, diet, dress and exercise. Pain should be relieved, not necessarily by drugs, but by sitz-baths, topical applications, heat, etc., or, if due to mechanical causes in the organs themselves, recourse should be had promptly to surgical intervention.

The conical cervix already described is so frequent a cause of dysmenorrhea that it should invariably be corrected when the attention of the physician is called to the characteristic symptoms.

It is better practice to do a full dilation, under anesthesia, supplemented with plastic work for the purpose of restoring the contour of the cervix and maintaining a proper lumen, than to subject the patient to a course of local treatments in the gynecologic chair. I believe, in fact, that the doubtful local benefit to be derived from such treatment is more than counterbalanced by the mischief of the procedure in fixing the girl's attention upon her pelvic organs and clouding her young horizon with the shadow of chronic difficulties.

With this in view I have been in the habit of subjecting my patient to but one seance, in which I aim to accomplish so much that she does not have to return for further local treatment. She is told that her difficulties have been corrected and is encouraged to believe that she is now cured and must in future keep herself well.

The operative work I speak of, "tracheloplasty," is applicable to all cervical deviations, deformities and displacements, and is undertaken to restore the anatomical relations of the organs and to re-establish normal function.

While conception and full-term pregnancy are theoretically to be desired in these cases, both as a means of developing the generative tract and remedying some of the imperfect conditions present, it is not always happy in its results. If the case goes on to full term, labor is apt to be arduous from lack of functional power in the organ, anatomical conditions, etc., and tears or trauma are exceedingly apt to occur with all the dangerous consequences. At best such a woman is sadly handicapped and, for her, wifehood and motherhood are hazardous experiments. If mothers and educators could be made to realize how preventable are most of the diseases from which the rising generation of women is doomed to suffer; if, for instance, they would reflect upon the fact that among the most prolific causes of gynecic disease are maldevelopment from improper hygiene at puberty, taking cold at the menstrual period, and constipation, the season of girlhood would henceforth be brought much nearer Nature's wise intention and would to a great extent cease to have its present significance to medical science.

The girl as the product of modern civilization is, in everything but bodily vigor, removed by all that is desirable from her aboriginal mother.

It is the just aim of our educational system to develop still further her intellectual qualities. It is therefore due to her and to the vital interests she represents that we endeavor to restore as far as is compatible with our artificial standards, the natural privileges of which she has been deprived, and contend with coming generations for better things.

103 State Street.

ADENOMA SEBACEUM OF THE NON-SYMMETRICAL TYPE.

WILLIAM S. GOTTHEIL, M.D.
NEW YORK CITY.

The pathologico-anatomical term adenoma still lacks both definiteness and circumscription. Some authorities extend it to include all increase of glandular epithelium, even when form and function are well preserved. Others limit the designation to an atypical increase with loss of function. It is not surprising, therefore, that the same confusion should exist with regard to the sebaceous adenomata of the skin. The affection is a rare one. and the opportunities for histological examination have not been numerous. A study of the literature, however, shows very plainly that two main pathological types may be distinguished. The first accords with Unna's definition: Benign, irregular, tumorous outgrowths of the sebaceous epithelium, going on to fatty, but not to corneous or colloid metamorphosis. The second is a simple hypertrophy of apparently normal sebaceous gland tissue.

Clinically, also, at least two types of sebaceous adenomata are to be recognized; they do not, however, correspond to the pathological types, cases of both occurring in either of them. Most of the recorded cases have occurred as multiple, yellowish or yellowish-red, firm pin-head to lentil sized nodules, without any central depression, and situated on the central portions of the face, more especially upon the nose, naso-labial folds. etc. A certain proportion of cases are congenital, and are therefore ranged by Besnier, Hallopeau, and Jadassohn among the nevi. Mental sluggishness or distinct deficiency has been noted in a number of cases.

In a few cases, however, sebaceous adenoma occurs as one or more larger tumors seated upon the scalp, or more rarely upon the back or other parts of the body. Barlow has found 50, and Poncet as many as 60. in one case; but usually they are single or few in number. They form lentil to nut sized or larger tumors of a pale yellowish color, and absolutely indolent. Microscopically they are composed, as a rule, of hypertrophied sebaceous epithelium enclosed in a distinct fibrous stroma. Hyaline and calcareous degeneration has been noted and even transformation into typical epitheliomata. It is a case of this kind that I desire to record.

The patient was a girl of 19, born in Germany. She was distinctly backward in physical development, looking like a girl of 14 or 15, but was mentally bright. She began to menstruate at 16, suffered from chlorosis three years ago, and had had leucorrhea for the past six months. The lesion on the scalp was first noticed when she was one year old; it was very small at first, and has gradually grown to its present size. There had been no subjective symptoms from the growth, and the patient simply desired to be relieved of the deformity.

The growth is not very well shown in the accompanying illustration, on account of its comparatively slight elevation above and color differentiation from the surrounding skin and blond hair. It was situated upon the right parietal region of the scalp, near the fronto-parietal margin and about half an inch behind the anterior margin of the scalp. It formed a curved, elongated patch two and a half inches long by three-quarters of an inch in its widest part. The surface was slightly elevated, a little rugose, and marked with a few lanugo hairs; normal scalp hair was entirely absent over it. Its color was a pinkish-yellow, quite distinct to the eyesight from the normal scalp. The entire mass formed an absolutely sharply circumscribed tumor in the skin.

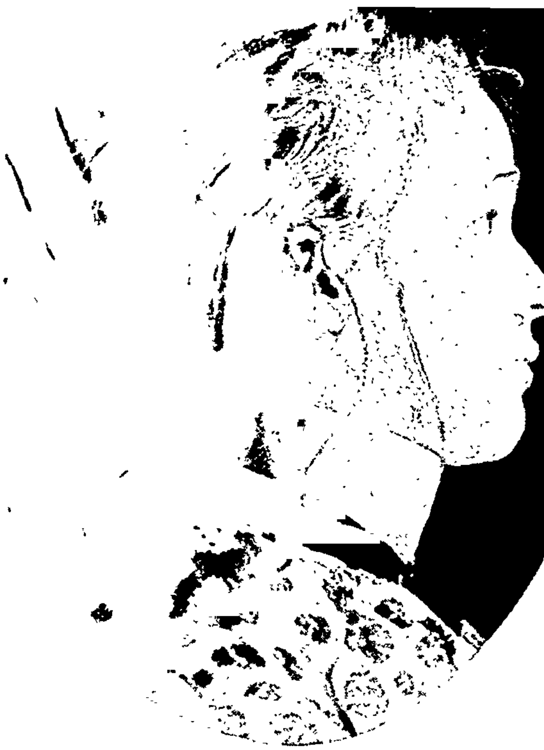


Figure 1.

The diagnosis was not made from the appearance of the growth; in fact Darier admits that it can not be made in the non-symmetrical form of the disease until the microscopic examination has been made. Before this was done I demonstrated the case as a probable xanthoma at the Manhattan Dermatological Society. After excision portions of the tumor were hardened and stained in various ways. I may note that the "Kernschwartz" gave me the best results for photomicrographic reproduction, giving all the gradations from light gray to black in a way eminently suited for the purpose.

The microscopic picture is shown in Figure 2. Its most marked feature is the enormous hypertrophy of the sebaceous glands, which are, however, normal in shape and have normal excretory ducts. Each gland is inclosed in a thin capsule of fibrous tissue. The epithelial layer is increased and the papillæ of the corium are hypertrophied; and here the growth resembles the benign forms of epithelioma to a certain extent. The isolated hair papillæ found in a few of the sections are very small and atrophic. The sweat glands and the subcutaneous connective tissue and fat are apparently unchanged, save for the compression exercised by the hypertrophied sebaceous glands.

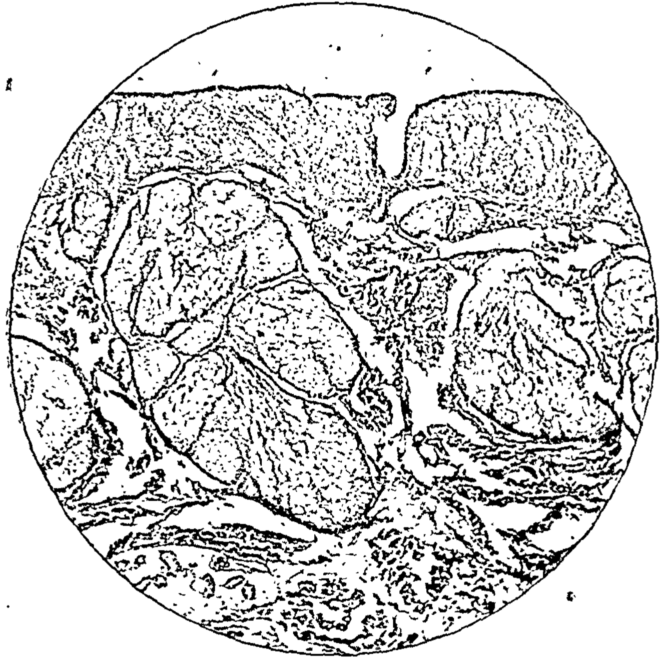

Figure 2.

The resemblance to rhinophyma is marked, but there is absence of any hypertrophy of the connective tissue of the cutis, and the increase of the epithelial layer is distinguishing. Benign epithelioma of the adeno-cystic type might be thought of but for the absence of epithelial prolongations and degenerated cell-nests.

THE TREATMENT OF LARYNGITIS.*

OTTO T. FREER, M. D.
Instructor in Diseases of the Chest, Throat and Nose, Rush Medical College; Professor of Laryngology and Rhinology, Chicago Policlinic.
CHICAGO.

It is the intention of this article to describe chiefly the local treatment of acute and chronic laryngitis, and to mention general measures only where they are necessary aids. The first form of acute laryngitis to be considered is the simple catarrhal type of moderate degree. This variety occurs chiefly in adults and, of all forms of laryngitis, is seen oftenest. It does not confine the patients to the house so that most of them are seen in the office or at clinics.

The chief symptoms are cough, at times incessant and distressing and varying degrees of hoarseness. The laryngoscopic appearance are the well-known ones of diffuse or localized congestion, especially of the cords, while secretion may be absent, or raised in the form of mucus or muco-pus. Most of these cases run but a short course and recover spontaneously, though the patient may continue to use and even abuse his voice. Where cough is a prominent feature it mechanically injuries the larynx and should be controlled by codein or other usual remedy. The influence of the inhalation of hot steam on the course of the disease has, in my hands, been so decided that I have come to rely on its beneficial influence. Voice rest is to be enjoined, but it is hard to enforce obedience. Of internal remedies, salicylate of sodium seems to have an abortive influence in some cases. With diaphoretics I have accomplished nothing, neither has menthol volatilized or sprayed in oily solution influenced the course of the affection as far as I could see. Seth Bishop praises menthol as an antiseptic anodyne. The anodyne effect is so feeble, in my experience, that it will not even suppress cough. The cooling sensation caused by the drug is deceptive. Menthol is, as Ingals says, chiefly an irritant stimulant and hence out of place in early acute laryngitis. As to its antiseptic influence it is doubtful whether the minute amount of this rather feeble antiseptic entering the larynx in volatilized form will influence the growth of microbes encased in protecting mucus. The oily menstruum of the spray will prevent efficient action of the antiseptic qualities of the remedy. This effect of oily solution on antiseptics is emphasized by John E. Weeks in his article on the relative germicidal value of the antiseptics. He thinks that the oily solvent prevents contact of the chemicals used, with the tissues.

Though most cases of the variety of laryngitis under consideration recover speedily, quite a number show little tendency to get well and pass into a tedious subacute stage with slow recovery or become chronic. Persistence in singing or speaking contrary to orders is one of the chief causes for this. In fact, it seems almost impossible to induce patients with acute laryngitis to rest the voice. Where the acute laryngitis assumes this protracted form local treatment is needed. Most cases will recover promptly under its influence, but some will prove refractory, especially where the general health is bad, as in the pretuberculous state or when lactation reduces nutrition.

The clinical picture and histologic appearances of acute laryngitis are those presented by an infected mucous membrane, whatever theories may be held in regard to the etiologic importance of exposure to cold, which probably acts merely as a predisposing cause. If we find the histologic changes of acute laryngitis, the epithelial and subepithelial round-celled infiltration, the desquamation of devitalized epithelium, the wandering of masses of leucocytes to the surface in any mucosa other than that of the respiratory tract, as that of the urethra or conjunctiva for example, we are not in doubt in the least that we have to do with a mucous surface inflamed by bacterial invasion. Why should exposure to cold, without other agent, be supposed to be able to produce changes in the mucous membrane of the larynx that elsewhere in the body we regard as typical of an infected mucous surface? The beneficial action of the usual remedies also impresses one with the infectious character of acute catarrhal laryngitis. These remedies are the so-called astringents, all of which are bactericides, and it has been my experience that the most bactericidal of all, nitrate of silver, is the most effective, and that the least in value are two but feebly antiseptic, tannic acid and alum. The most effective astringents are metallic antiseptics, and differ from organic antiseptics in their power of combining with the surface of the living tissues and imposing a barrier of metal-laden protoplasm to bacterial invasion. They therefore do not merely lie on the epithelium, but enter into it so that prolonged contact is insured. If used in too great strength they will devitalize the surface, that is cauterize it, a result irritating and undesirable in acute inflammations.

---

* Read in the Section on Laryngology and Otology, at the Fifty-second Annual Meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901.

This clinging power of the metallic salts to the tissues undoubtedly explains the permanence of their beneficial and also undesirable effects, such as lead poisoning and argyria. One of the unpleasant features of the silver salts is this latter quality, and Moritz Schmidt tells of three cases of argyria due to persistent swabbing of the throat for months with silver nitrate. As to the so-called astringent effect of the astringents, as Harnack says, it does not exist. They do not cause a mysterious contraction of the tissue elements or their vessels; they merely form a protecting coat which hinders the egress of secretion—hence the drying effect of astringents.

At present silver nitrate is largely being displaced by protargol and similar modern compounds of silver, which are undoubtedly superior to the nitrate. Protargol is antiseptic, does not cauterize and penetrates the tissues deeply. A good strength of solution for use in acute laryngitis is from 20 to 50 grains to the ounce. Protargol and the astringents seem to me most effective where there is a decided amount of purulent secretion, while in the cases where hyperemia predominates the result is much less marked. Some of these latter cases are, in fact, in some instances not so much laryngitis as congestion due to voice abuse, especially in singers. This has been well emphasized by Holbrook Curtis of New York. Results are best obtained here by voice rest and proper methods of singing.

I have not found that the remedies of the eucalyptol, thymol, menthol and terbene group compare in efficiency with the metallic astringents. They are often used in oily solution and, as mentioned, oily menstrua inhibit the action of antiseptics. In addition oils do not form intimate contact with the moist tissues treated, but spread and float away as they would on water. The conditions are different on the skin, designed naturally for oily media, and where prolonged contact is assured. The above-mentioned drugs belong to the class of feebler antiseptics and therefore require prolonged contact in decided strength to be effective.

The mode of application of remedies is not a matter of indifference. The spray seems to me the best. Powders are removed by coughing and scraping before the active drug they contain has time to dissolve and penetrate the layer of mucus that protects the epithelium. Swabs mechanically injure the tissue by causing violent spasm of the laryngeal muscles and scraping off the epithelium, leaving raw surfaces. The laryngeal syringe, to reach all parts, must inject a large amount of fluid which can therefore not be used in proper strength to be effective without causing the patient great discomfort. With the spray a single drop can be made to evenly cover a large surface. The spray should of course always be introduced under the guidance of the laryngeal mirror, but even then its fault is that enough does not get into the narrow space found in many patients between the epiglottis and posterior pharyngeal wall, in sufficient amount to be effective. To open the upper larynx widely for the spray in these cases it is a good practice to hook the epiglottis forward with the tip of the atomizer. In many cases this is not possible, however, with the ordinary laryngeal tip, so that I use one of my deep tracheal spray tubes, recently described in The Journal, for this purpose. The long tube readily hooks up the epiglottis. Another advantage of the instrument is the fact that it is possible with it to spray directly against the interior of the larynx and so blow away mucus from the surface while driving the remedy against the tissues at short range. The perspective does not permit us to appreciate how very far down in the neck the larynx is often situated, and a spray coming from high above it in the ordinary way spreads like a fan, so that but a portion of the medicament enters the larynx, and the rest is lost on the pharyngeal walls and in the fossa pyriformis.

From the milder type of laryngitis mentioned we advance through grades of increasing severity until we reach an extreme type of acute laryngitis, acute submucous laryngitis. In this form the infectious agents pass beyond the mucous membrane into the lymph spaces and channels of the submucous connective tissue, which becomes swollen and hyperemic, while at times enlarged cervical lymphatic glands can be felt. In the upper larynx the swelling may be so great as to cause serious dyspneas due to enlargement of the epiglottic and aryepiglottic folds. In this type of laryngitis it is obvious that the affection has penetrated too deeply to be influenced by applications to the laryngeal mucosa, as the disease is more in the lymphatic channels than on the surface; in fact the irritant effect of astringents may add to the swelling in a dangerous degree. In these cases the external application of cold to the neck is efficacious. As Schech states, cold limits the blood supply to the larynx by constricting both the great and small arteries of the neck, as proven by Winternitz. This diminishes the vascular swelling of the mucous membrane. In the case of a patient shown at the clinic for chest, throat and nose diseases, at Rush Medical College, the dyspnea was so great that tracheotomy was considered. The patient was admitted to the Presbyterian Hospital and treated with a spray of adrenalin chlorid applied systematically, together with repeated hypodermic doses of pilocarpin, 1/4 grain each, to keep up a profuse sweat. These means seemed to keep the swelling in check, so that operation was avoided.

The hypodermic use of pilocarpin for edematous conditions of the larynx has been advocated by Suarez de Mendoza, and he thought that it avoided tracheotomy in threatening cases. Felix Semon obtained good results from scarification of the swollen mucosa in these severe examples of submucous laryngitis. Intubation proved ineffective in a case of my own, as the edematous aryepiglottic folds closed over the top of the tube; scarification also proved unavailing so that tracheotomy had to be performed. When the epiglottis is much swollen it is apt to be immovable, so that fluids enter the trachea. In this state it is advisable to feed with the esophageal tube. In some instances submucous laryngitis is confined to the hypoglottic region, the loose areolar tissue underneath the cords swelling and dangerously obstructing respiration, the so-called laryngitis hypoglottica acuta gravis of Naether, or chorditis vocalis acuta inferior as it is also called. This grave form occurs chiefly in adults, while a less serious variety is found in children, causing the condition called pseudocroup, laryngismus stridulus, or spasmodic croup. Though often this affection is caused by spasm of the glottis merely, the opinion of to-day seems to be that at least most of the cases are due to temporary hypoglottic swellings that increase during the venous congestion due to sleep, and subside as soon as the waking child takes deep inspirations. The swelling has been seen by a number of observers. In some cases intubation is needed, but as a rule cold applications to the neck, keeping the air moist with steam and the use of narcotics to avoid any complicating spasm of the glottis will avert this. Local applications to the hypoglottic region in children are impossible.

The acute hypoglottic laryngitis of adults is apt to require tracheotomy or intubation, and neither of these operations should be put off if dyspnea is at all marked, as the hypoglottic swellings are apt to suddenly increase enough to suffocate the patient. Cold applications to the neck will prove useful. Hajek warns against the use of potassium iodid in this affection, as it may make immediate tracheotomy needed by adding to the swelling. Laryngitis with scabbing and crusting in the larynx, the so-called laryngitis sicca, exists not merely in a chronic but also in an acute and subacute form. It is hard to explain this tendency of the secretions to dry in the larynx. The crusts may become massive enough to cause serious dyspnea, but usually are merely sufficient to create cough and hoarseness and at times bleeding.

Cases of this kind are not excessively rare, and usually the crusts can be seen to extend down into the trachea. As a rule the scabs rest on the cords and inter-arytenoid region, where there is pavement epithelium. These cases are generally tedious without treatment both to the larynx and trachea. As long as the latter is lined with crusts treatment confined to the larynx is ineffective. Inhalation of normal salt solution from a steam atomizer is an excellent palliative, but will have little effect on the tracheal scabs. Nitrate of silver or protargol sprays, as soon as the disease has passed its acutest stage, are very effective if they can be made to reach all of the diseased mucosa. The ordinary laryngeal tip will answer well enough for most cases confined to the larynx, but for the tracheal scabbing I have found it necessary to use the long tracheal spray tube devised by me. The tip of this must be either held within the opening between the cords or passed through them into the trachea after cocainization. The ordinary spray tip has to be placed so far above the chink of the glottis that most of the jet is lost in the larynx and but little passes into the trachea, especially as the cords are held spasmodically in a position of partial adduction by most patients. Until I used this method I found laryngotracheitis sicca a discouraging disease to treat. The tracheal syringe is far more unpleasant for the patient than the spray, and as it necessitates larger amounts of fluid the concentration of the chemical in solution must be weaker unless we wish to run the risk of causing excessive irritation. The spray also applies itself more evenly to the tracheal walls. Oily substances can be sprayed into the trachea with the view of dissolving the crusts, and the patient should be kept in a room with a steamy atmosphere.

Laryngitis characterized by hemorrhage from the mucous surface without ulceration or wound, and at times by submucous hematomata, is called laryngitis hemorrhagica. It is very rare and in some cases has proved dangerous on account of large tough clots forming in the trachea and larynx. In a large proportion of cases it accompanies laryngitis sicca. The bleeding may be profuse. In laryngitis sicca the recurrence of the bleeding can be avoided by moist inhalations to prevent the formation of crusts. Astringent applications in laryngitis hemorrhagica should not be irritating, and the best of these for mild hemostatic effect is probably tannic acid. The iron salts will certainly create much reaction and form tough leathery clots hard to remove by coughing. When the larynx is full of clots and blood it is doubtful whether any local applications will reach the bleeding surface, so that cold to the neck, rest and narcotics are probably the best remedies under these conditions. Adrenalin would have a good but temporary effect when it can be applied.

Uchermann has recently described a form of laryngitis which he calls laryngitis acuta circumscripta nodosa rheumatica. It occurs in the form of sensitive, rather firm, blue-red infiltrations analogous to those of the cutaneous erythema nodosum. When seated over the crico-arytenoid articulation the nodes cause pseudoanchylosis with immobility of the cord. The therapy is salicylate of sodium.

In chronic laryngitis we have to deal with lasting changes which have gradually more or less profoundly altered the epithelium, the submucous connective tissue and the blood-vessels of the larynx. These elements will be effected in varying proportion. The epithelial changes are usually in the direction of the creation of a dermoid condition of the laryngeal mucosa. In extreme cases the whole laryngeal interior becomes thus lined with pavement epithelium, but usually there is thickening merely of the inter-arytenoid epithelium and of that on the cords. At times the change is confined to the region of the processus vocales, causing two epithelial protuberances, the typical pachydermia laryngis of Virchow. When occurring in the inter-arytenoid region the epithelical thickening causes stiff folds or a general warty prominence of this locality. The connective tissue hyperplasia may cause smooth or nodular hypertrophy of the cords, greatly increase the size of the ventricular bands, which then cover the cords, create hypoglottic swellings that at times dangerously interfere with breathing, fill the inter-arytenoid space with clumsy folds and nodosities of thick mucosa. Hyperplastic mucous membrane protruding from the ventricle of Morgagni has given rise to the term "eversion of the ventricle," a false conception of the condition. The vascular changes are in the direction of venous dilatations which form, at times, varices on the cords. There may be venous congestion of the entire laryngeal membrane.

In other cases of chronic laryngitis there is atrophy instead of hypertrophy. In my experience a not very rare condition is absorption of the tendon-like connective tissue of the cords, leaving in their place mere folds of flabby mucous membrane, an incurable state well described by Störk. In some rare cases erosions on the cords and fissures of the interarytenoid region are found. They are always suspicious of tuberculosis. In some old cases of laryngitis atrophy of the muscles occurs simulating paresis.

Most cases of chronic laryngitis do not show these profound alterations. In many cases the condition is slight and localized, especially in the chronic laryngitis of singers.

In another type of cases the most prominent changes are found in the mucous glands, with chronic alteration of secretion, in mild examples limited to scraping up of small amounts of muco-pus. In the severer grades the whole larynx and trachea may be lined with pasty pus or thick crusts, at times fetid, the so-called ozena laryngis, usually but not always associated with the same state in the nose and nasopharynx. When the secretions are removed the shape of the laryngeal interior may be found but little altered. In some extreme cases the vocal cords will be found distorted and joined to each other by cicatrices, leaving but small room for breathing, as described by Freudenthal.

This brief sketch of the pathologic conditions of chronic laryngitis shows their enormous diversity and the great variety of means needed to combat them, ranging from a mild astringent to a surgical operation, and that one must be able to recognize states in which irremediable changes make all treatment useless. The need of treating simultaneously nasal and pharyngeal pathologic conditions is too well known to need more than mention here. The great and inveterate effects of chronic laryngitis can not be conquered by a few spray formulæ, as the favorite presciption corner of some medical journals would lead one to think. Great patience is needed by the patient and physician and we can not promise too surely a recovery. Often we will get only moderate or no improvement.

The first thing needed in the treatment of chronic laryngitis is to remove the source of chronic laryngeal irritation if there is one, whether it be mouth-breathing, nasopharyngeal catarrh, alcoholism, voice-abuse, or other cause. It is very important to bring the body weight and nutrition up to the normal standard for the individual. This is unfortunately not alway possible when we consider how often chronic nontubercular laryngitis depends on pulmonary tuberculosis.

In the milder cases of chronic laryngitis, where the changes are confined to slight epithelial thickening and hypersecretion with moderate congestion, we can sometimes effect rapid improvement by the stimulus of mild astringent applications, such as silver nitrate, 10 grains to the ounce, or copper sulphate, 20 grains to the ounce. From the much praised alumnol I have had only disappointment, but zinc sozo-jodole, recommended by Moritz Schmidt, is mild in action and gives positive results. I use it in 5 per cent solution. This treatment is gratifying in the slight chronic catarrhal irritations of singers. Singers are subject to these even when they use their voices properly, and seem to have a special tendency to laryngitis.

In instances where the epithelial thickening and connective tissue hyperplasia is pronounced we need more powerful chemical agents to accomplish our ends. Those authors who have had the widest experience and have acquired an unusual degree of intralaryngeal skill in consequence advise here the application of mildly caustic solutions applied accurately to the parts showing pathologic changes, as for instance thickened hyperplastic *vocal cords or the pachydermatous folds in the inter-arytenoid* region. Solutions of silver nitrate in the strength of 25 to even 240 grains to the ounce of water are advised by Störk, Krieg, Schroetter, Semon. *Tincture of iodin*—pure—and chlorid of zinc in 3 to 5 per cent. solution are examples. Sajous even employs fused chromic acid to destroy completely the thickened epithelium and ectatic veins on the vocal cords; with good results. Störk says that silver nitrate should be used in strength sufficient to whiten the surface treated. Where the pathologic changes are marked and where we must cause destruction of epithelium which is unnatural to its location such severe means are needed and will be better borne than by the healthy larynx, but it is well to follow Semon's advice and begin with the milder solution, and only if nothing is being accomplished to work up to the stronger ones. It is better not to cover too much ground at one sitting, as severe reactions are to be expected; in fact, Störk says that the patient will be voiceless for a few days, and suggests that this enforced silence will be beneficial. He and others advise a sojourn in a resort, for some cases, simply because the patient will not have the usual opportunities for conversation. For these strong applications local anesthesia is *needed as a preliminary*, and the application of the astringent must be made with a small swab under the guidance of the mirror, with perfect accuracy. As Ingals says, the strong solutions are in most cases objectionable, because of the spasm of the larynx and the great discomfort they cause the patient. In some cases of marked chronic laryngitis, however, we can not avoid their use if we wish to accomplish anything.

Where hyperplastic mucosa protrudes from the ventricle it must be cut away. The best instrument for this purpose is the double curette of Landgraf and H. Krause, which cuts vertically. Tuberous masses in the inter-arytenoid region, elephantiastic ventricular bands can also be removed by some one of the double curettes, or can be reduced by electrolysis or the galvanocautery. The cutting operations are to be preferred, however. *In some cases the snare can be used.*

The treatment of the typical pachydermia laryngis of Virchow, the cushion-like epithelial masses growing from the processus vocales, likened properly to corns in the larynx, is regarded as very unsatisfactory. The accompanying chronic laryngeal catarrh may yield to remedies, but the pachydermatous outgrowth will remain. Some advise against interference with these growths where they do not injure the voice perceptibly. Chiari thinks they should be removed as they are occasional sources of perichondritis. If partly cut off with the double curette they will return; if deeply removed we may do injury to the processus vocalis. The cautery, electrolysis, tincture of iodin, chromic acid, have all been used with poor success. Scheinmann employs a spray of 2 to 3 per cent. acetic acid inhaled from a steam-atomizer for ten minutes three times a day. He also injected the same solution from a laryngeal syringe. The proceeding does not seem very logical, and his claims that the pachydermatous nodes softened and grew smaller were not confirmed by Ilberg, who also had no success with applications of 0.5 to 5 per cent. solutions of caustic potash.

Fein's method is the most promising. He caused disappearance of the pachydermia by using a solution of salicylic acid, 15 grains, water and alcohol each 75 minims, applied with a swab. There was no reaction. The remedy was used every other day for three months. For the treatment of chronically swollen vocal cords softened by venous dilatations Krause's incisions or scarifications offer a decided advance over previous methods. Krause uses a lance-shaped knife and makes small incisions 3 to 4 millimeters apart, longitudinally, along the cords from the anterior commissure to the processus vocalis. The incisions pass through the entire thickness of the vocal cords. In Krause's reported cases the result was recovery from chronic conditions that had resisted astringents for months.
